The third aspect of psychiatric function in the general hospital grows as the service becomes established; it is consultation. The accuracy of diagnosis and effectiveness of treatment mount as personal factors become known and controlled. When physicians with different backgrounds and viewpoints get together, they combine their data and points of view to the advantage not only of patients but of each other. When this happens, the dichotomy that has isolated psychiatrists from their medical colleagues, to the disadvantage of both, rapidly disappears. This consultation service begins to define personal problems and to provide direct and positive treatment approaches. It saves unnecessary reiteration or detail in diagnostic studies when a physician intensifies his search for a patient's illness where it does not exist. It reduces the incidence of mistaken surgery. It wins cooperation with and acceptance of necessary medical and surgical procedures when patients are ignorant, apprehensive, or uncooperative. It helps nurses and other personnel understand patients as people, and, thus, it brings better understanding to the handling of sick, discouraged, and apprehensive patients.

The fourth aspect of psychiatric function is outpatient service. As this is developed, frequently in the interview offices provided for inpatient use, the period of necessary inpatient care is decreased, and, thus, the expense of treatment is reduced. Very logically, the development of social service extends from medical social work to coordination with community services and to assistance to therapeutic programs carried on in the outpatient department. The scope and organization of the outpatient department varies considerably in relation to the population and social nature of the area in which the hospital is located.

Special consideration should be given to the place of neurology. In smaller hospitals, this is probably best managed on the general medical wards. If a hospital is large enough to have a neurological grouping of patients, it is often advantageous to have the service linked with the psychiatry service, but it appears inadvisable to have neurological and psychiatric patients on the same ward. Except in hospitals having highly specialized services, psychiatrists are often the physicians with the most neurological background, and they must always be prepared to detect and deal with organic lesions in the patients under their care. Their association with physical and occupational therapy and their ability to handle reactions to handicaps also make the link of psychiatry with neurology desirable.

PSYCHIATRY AND PEDIATRICS

Development of a psychiatric service in a general hospital is especially beneficial in the field of pediatrics. Children must always be considered in their usual environment, particularly when temporarily removed from it by illness. They react so intensely to interpersonal difficulties at home that their emotional reactions must always be evaluated when their total health picture is being considered. They relate to each other so actively when grouped together that there is always need for understanding and skill in human relationships. As their emotional symptoms are often indications of difficulty in the lives of their parents, there is need for effective work in the homes by physicians, nurses, and social workers. Play therapy rooms are important adjuncts to both pediatric and child guidance services.

PERSONNEL AND PROGRAM

The staffing of psychiatric services is extremely difficult at the present time. There is an over-all shortage of physicians, and a much more intense shortage of those specially qualified in the field. The older men have little organized opportunity to learn psychiatry at the community level, and those whose experience has been relatively limited to the care of adults and the mentally ill often have limited background in pediatrics. Present day training programs call for diversity of experience and work with children, so that the younger men are being better prepared for this type of work. There still is, however, a great scarcity, and there is the risk that, although a well-appointed service can be set up, there is no one to run it. There is a certain law of supply and demand operative in medicine. The demand for this type of service is increasing so rapidly that the supply is bound to increase. The educational opportunities for those wishing to go into this field are vastly superior to those available 10 or 15 years ago.

In addition to the psychiatrist, nuclear personnel are the clinical psychologist, psychiatric social worker, occupational therapist, and nurse. These persons should be selected with a view to their warmth of interest in people and personal problems and to their own stability as well as their capacity to team up with others and their experience in community work.

The problem of nursing is one that requires both study and foresight. There have not been many psychiatric sequences available for general duty nurses. Many of them, particularly in recent years, have had three months' training in a state hospital while students. Graduate experience is desirable for this type of work, and nurses who have had it are not plentiful. Any hospital that plans to develop such a service would be wise to select a nurse with suitable attributes of personality, leadership, and interest in this field and to give her opportunity to prepare for this type of work. Such a nurse will be better able to take charge of this program than one who has had only experience in general duty.

There should be considerable flexibility and local variation in the development of psychiatric services. Principles can be stated, but the development should be appropriate to the hospital as it exists and functions and to the nature of the hospital's relationship and responsibilities to the community. Because there is a certain element of pioneering involved, those working in the hospital may desire to discuss their work with and be advised by consultants from various professions concerned. They should also make visits to other services of this type to gather ideas. It is particularly important in the architectural planning that the program be determined in advance and discussed carefully with professional personnel who have worked in such programs. The plan should also be reviewed with architects. Care should be taken to work from the functional needs of the program rather than from the existing design of the hospital or the traditional concepts of hospital construction, which were developed in an era when this phase of medical work was given scant consideration. The trend toward provision of psychiatric facilities in conjunction with other medical services is so strong that any hospital big enough to be subdivided into services or departments should seriously consider providing a psychiatric service, for, no matter what the detail of treatment, every aspect of medical practice fundamentally comes back to the personal level: the treatment of people by people.

USE OF ANTIBIOTICS IN NONBACTERIAL RESPIRATORY INFECTIONS

Capt. Philip N. Jones, Major Roy S. Bigham Jr.
and
Lieut. Phil R. Manning, (MC), U.S.A.F. Chanute Air Force Base, Ill.

The discovery of the sulfonamides and antibiotics is one of the most brilliant pages in the history of medicine. Many bacterial and rickettsial diseases that formerly were fatal are now treated successfully with antibiotics in a relatively short time. The outstanding success with bacterial and rickettsial infections has not been paralleled in the antibiotic treatment of viral diseases. Antibiotics are effective against the viruses that cause psittacosis, lymphogranuloma venereum, and trachoma and appear to be of value in the treatment of viral pneumonias.[1] It is generally conceded, however, that the use of antibiotics in acute nonbacterial respiratory infections and influenza is of no benefit in the treatment of the primary disease.[2]

The most important viral-like conditions with regard to incidence and economic importance are moderately severe, acute illnesses that are loosely grouped with certain bacterial conditions as acute respiratory infections. During outbreaks of so-called acute respiratory infection simultaneous increase in both the bacterial-like and viral-like syndromes is commonly observed. It is also common to encounter the use of antibiotics in almost all patients despite the absence of any proof of specific value of these agents in the nonbacterial syndromes. Antibiotics are given with the hope of preventing secondary bacterial infection in those patients who do not have bacterial infection when first seen. Since little or no specific therapy is available for the common viral-like respiratory syndromes, any measure that will limit or minimize the duration of the illness is important.

During the early months of 1952, two of us (R. S. B. and P. N. J.) observed an outbreak of respiratory disease in which there were a number of cases that later proved to be type B influenza. Secondary bacterial invasion was not considered in study of these cases, but analysis of the group, which included known influenza, the common cold, tonsillitis, pharyngitis, bronchitis, and bacterial and viral pneumonias, suggested that antibiotic therapy had no effect in the influenza-like cases.[3]

During an epidemic of type A' influenza in the early months of 1953, we had the opportunity to observe a second outbreak under conditions comparable to those that existed the previous year. Again, a large number of cases of respiratory disease developed over a short period of time, with both viral-like and bacterial-like syndromes. Several hundred of the patients admitted to the hospital presented an influenza-like clinical picture

on admission. Since these patients had been in close contact under normal living and working conditions with those presenting the bacterial-like conditions and since all were admitted to respiratory wards, it seemed likely that so-called secondary bacterial invasion might occur. This report concerns our investigation of the value of antibiotics as prophylaxis against complications in the nonbacterial influenza-like syndrome. We also studied the efficacy of antibiotics as primary therapy in patients with this syndrome.

CLINICAL PROCEDURE

All patients with respiratory disease were admitted from the dispensary to open respiratory wards after a white blood cell count and a throat culture were taken. All were given a uniform schedule of saline gargles, phenylephrine hydrochloride nose drops, and forced fluids. In strict order of admission to the ward and prior to examination by the physician, each patient was immediately placed on one of three treatment schedules by the ward nurse. These schedules consisted of the administration of capsules identified as 1, 2, or 3, to be given every six hours. They contained acetylsalicylic acid (aspirin), 600 mg., oxytetracycline (Terramycin), 500 mg., and erythromycin, 200 mg., respectively. The supply of erythromycin was used up in the study, and in the later phases new admissions were alternated between schedule 1 (acetylsalicylic acid) and schedule 2 (oxytetracycline). The ward nurse and patients were not aware of the contents of the capsules, but the physician always knew which drug was being given to each patient. The ward physician was authorized to remove a patient from the series if there were clinical signs of bacterial infection on initial examination. Bacterial infections consisted almost entirely of exudative tonsillitis or pharyngitis that later proved to be due to beta hemolytic streptococci. Some bacterial pneumonias were also observed. In a few cases changes in therapy were dictated by bacteriological or radiological studies, which were taken on admission but were not interpreted until the second or third day of hospitalization. These patients were also excluded from the series. Patients were not excluded from the series on either physical findings or laboratory findings subsequent to those on admission.

Patients selected for this study had some or all of the following complaints on admission: headache, lumbar backache, general muscular aches, fever, nonproductive cough, and mild sore throat. Some also complained of nasal congestion. All were admitted within 12 to 18 hours after onset of symptoms. The physical findings were limited to a mildly swollen pharynx and a fever ranging from 99.4 to 105 F. All patients with exudative pharyngitis or tonsillitis on admission were excluded as were those whose initial throat culture was abnormal. Normal throat flora was considered in this group to include diphtheria cocci, Neisseria catarrhalis, and Staphylococcus aureus. Thirteen patients showing nonhemolytic streptococci were included because of low leukocyte counts and a viral-like clinical history. Patients whose throat cultures showed hemolytic streptococci were excluded. An arbitrary maximum initial leukocyte count of 8,500 per cubic millimeter was established for inclusion in the group. Only two patients with higher counts (10,050 and 11,500) were accepted; these patients had type A′ influenza shown serologically. The leukocyte counts ranged from 3,800 to 8,500 per cubic millimeter and averaged 6,355 per cubic millimeter.

Sixteen of the patients in this series were selected at random for serologic studies for influenza. With the use of paired serums of acute and convalescent infections, a fourfold to twelvefold rise in titers for type A′ influenza was found in 11 of the 16 cases. The leukocyte counts in these 11 cases ranged between 4,900 and 11,500 per cubic millimeter and averaged 7,095. While it was not feasible to do serologic studies on more than a small percentage of the patients admitted, the clinical pattern in all of the cases was similar, and we suspect that a majority of the patients in the study had type A′ influenza. For the sake of accuracy, however, the condition is referred to as a nonbacterial influenza-like syndrome.

After all patients were eliminated who failed to meet the arbitrary criteria as established for this influenza-like syndrome the records of 150 patients were left for examination. Of these, 76 received oxytetracycline, 54 received acetylsalicylic acid, and 20 received erythromycin.

As the findings of physical examination and laboratory studies were normal except for a slight pharyngeal congestion, a patient's statement of his symptoms and the temperature response were the only criteria available for evaluation. Subjective symptoms and fever were closely associated in that all of the patients felt entirely well when their temperature returned to normal, except that some had a residual tiredness and a persistent dry cough. Length of hospitalization could not be utilized as a criterion since the minimum hospitalization necessary had been set at five days. Accordingly, the most objective and accurate measurement of response was judged to be the course of the fever. Temperatures were taken at intervals of 6 hours, but we adopted 12 hour periods for purposes of determining the response. Temperature was considered normal when it fell to or below 98.8 F.

TABLE 1.—*Average Response to Therapy of 150 Patients with Nonbacterial Respiratory Infections*

Drug	Total No.	Patients, %	Average No. Hours to Become Afebrile
Oxytetracycline (500 mg. every 6 hours).....	76	50.7	41
Erythromycin (200 mg. every 6 hours).......	20	13.3	42
Acetylsalicylic acid (600 mg. every 6 hours)..	54	36.0	30
Total....................................	150	100.0	37

RESULTS

Among the 150 patients the elapsed time between admission and return of oral temperature to 98.8 F or below ranged from 12 to 120 hours, with an average of 37 hours. In the group treated with acetylsalicylic acid the return to normal temperature averaged 30 hours. The group receiving oxytetracycline averaged 41 hours, and the erythromycin treated group averaged 42 hours between admission and return of the temperature to normal (table 1). Disappearance of subjective symptoms corresponded closely to return of the temperature to normal with the exception of persistent cough. There was no indication that cough was less severe or prolonged in any therapy group. In the 11 cases of proved type A′ influenza the average time between admission and return of oral temperature to normal was 51 hours. The average was 54 hours in the six patients who received acetylsalicylic acid and 48 hours in the five patients who were given oxytetracycline. Differences in time of response were not significant (table 2).

After the temperature returned to normal no patient had a recurrence of symptoms or any sign of bacterial infection before discharge from the hospital, and no pathogenic organisms were found in throat cultures taken at the time of discharge. In five patients (four in the oxytetracycline therapy group and one in the acetylsalicylic acid therapy group) single isolated asymptomatic elevations of temperature to 100 F occurred 24 hours after the temperature had returned to normal.

TABLE 2.—*Average Response to Therapy of Patients with Serologically Proved Type A′ Influenza*

Drug	No. of Patients	Average No. Hours to Become Afebrile
Oxytetracycline (500 mg. every 6 hours)....	5	48
Acetylsalicylic acid (600 mg. every 6 hours)	6	54
Total.......	11	51

COMMENT

It is evident from these observations that neither oxytetracycline nor erythromycin altered the course of the disease. Indeed, the patients who were given acetylsalicylic acid usually felt better sooner than those who were receiving either oxytetracycline or erythromycin. There was no recurrence of symptoms or evidence of secondary bacterial infection in any of the patients.

It might be argued that the use of the antibiotics is beneficial in prevention of bacterial infections that might complicate a nonbacterial infection. In our patients suffering from an influenza-like syndrome no secondary bacterial infection was recognized in either the group treated with acetylsalicylic acid or the groups treated with antibiotics. It is, of course, advisable to use an appropriate antibiotic whenever a secondary bacterial infection occurs, but statistically the routine use of antibiotics for the prevention of these secondary infections does not appear justified.

Many studies have shown that antibiotics can be harmful as well as beneficial.[4] Serious, even fatal, infections may occur with either fungi or nonsensitive bacteria that are ordinarily saprophytic until the normal bacterial flora is altered by an antibiotic. While it is true that this adverse response usually occurs only with prolonged use, the potential danger exists.

The cost of antibiotics as compared to that of acetylsalicylic acid should also be considered, both in military practice and in civilian practice. The average retail cost of a capsule of oxytetracycline is 35 cents; a tablet of erythromycin costs 32 cents; and an acetylsalicylic acid tablet costs approximately 1 cent. The overwhelming percentage of savings should be kept in mind in view of the extensive use of antibiotics for treatment of nonbacterial influenza-like syndromes. If there was any benefit to the patient, even though small, the expenditure of funds for antibiotics would be justified. As the patient derives no benefit and is even subjected to a slight risk of complications from such therapy, the routine use of these drugs in nonbacterial infections is not justified.

There is no doubt that the same symptoms seen in these patients with a nonbacterial influenza-like syndrome may frequently precede a bacterial infection. In most cases the initial physical examination and white blood cell count will clearly differentiate bacterial from nonbacterial infections. It is, of course, necessary for the attending physician to make certain that a disease truly responsive to specific antibiotic therapy is not present.

SUMMARY AND CONCLUSIONS

Treatment with acetylsalicylic acid (aspirin), oxytetracycline (Terramycin), or erythromycin was divided among 150 patients with a nonbacterial influenza-like syndrome. The dosage consisted of acetylsalicylic acid 600 mg., oxytetracycline 500 mg., or erythromycin 200 mg. every six hours.

Paired serum samples were drawn at random from 16 patients for serologic study. Eleven patients had type A′ influenza. Although serologic identification of the disease was not obtained in the entire group, the clinical picture and course was similar in all cases studied.

Of the 150 patients, 54 were treated with acetylsalicylic acid, 76 with oxytetracycline, and 20 with erythromycin. The interval from admission to return of the temperature to normal averaged 37 hours for the entire group. The time required for return of normal temperature in the group treated with acetylsalicylic acid averaged 30 hours, in the group treated with oxytetracycline 41 hours, and in the group treated with erythromycin 42 hours. It would appear from this data that the antibiotics oxytetracycline and erythromycin had no influence on the course of the disease.

Of the 11 patients who were proved serologically to be suffering from type A′ influenza, six were given acetylsalicylic acid and five were given oxytetracycline. In these patients the average interval from admission to return of the temperature to 98.8 F was 54 and 48 hours respectively.

No secondary bacterial infection was observed in this series, in either the group treated with antibiotics or the group treated with acetylsalicylic acid. Thus it appears that administration of antibiotics routinely to prevent such secondary bacterial involvement is not justified statistically. If a secondary infection develops the appropriate antibiotic should, of course, be employed.

THE FAMILY PHYSICIAN AND THE PUBLIC HEALTH DEPARTMENT

CHAIRMAN'S ADDRESS

Vlado A. Getting, M.D., Dr.P.H., Ann Arbor, Mich.

With the rapid progress in medical and social sciences there have been concurrent changes both in the private practice of medicine and in public health practice. The family physician has the advantage of new drugs such as the antibiotics, cortisone, and isoniazid. Because of improvement in transportation, new diagnostic aids, improved laboratory procedures, and in some instances because of the changing pattern of medical practice, physicians can now see more patients a day. The work of the health department has been affected not only by these factors but also by the changing pattern of community life. The shifting of the population from rural to urban areas, the more recent trend of the decentralization of large metropolitan areas, and the development of large suburban communities have caused changes in the health department program.

The development of industry and shopping centers in suburban areas, the need for intensive specialization in complicated production methods, and the loss of production through absenteeism in industry have all made both management and labor more interested in the health of the worker. With the increasing interest of the public in health, development of community action through the formation of new voluntary organizations for various health purposes, and increasing governmental expenditure for health, it is time to evaluate the relationship of the family physician and the public health department.

HEALTH AN INDIVIDUAL RESPONSIBILITY

The individual will always be responsible for obtaining personal health services. There is general agreement that an educated person will do more for his health and the health of his family than can be done for them. In the past, measures for health maintenance demanded only limited individual responsibility. The development of pure water supplies, adequate sewage facilities, pasteurization of milk, and other sanitary programs were achieved through community action in which the individual may have participated as a citizen but was required to take no further initiative. In the future, however, there will be a need for greater individual responsibility in protecting one's health. Good health cannot be taken for granted, and the public is being rapidly educated to seek early medical care. It is the individual who must visit the physician for early care and who must avoid overweight, alcoholism, reckless driving, and home accidents. These things he must do for himself; they cannot be done for him. The individual, however, needs not only information but motivation; he must be convinced to seek what he knows is good for him and his family. Personal health services, therefore, are to a large extent determined by the individual's knowledge, by his attitude, and by the action he takes in obtaining necessary services.

The family physician is more than ever before in the front line of preventive medicine and health maintenance. He has an unusual opportunity to be of service to his patients and through them, to the community as a whole. The private practitioner has certain responsibilities to his patients. He must provide rapid diagnosis to determine the patient's need for preventive, therapeutic, and rehabilitative care. He is responsible for seeing that the patient receives the best care possible. The general practitioner should undertake no services for which his qualifications and facilities have not thoroughly prepared him. The patient must be considered not only as an individual but also as a member of a family and a community. The physician must understand the social and economic factors that contribute to his patient's health or illness. Continuity of care is important if the patient is to be afforded the best possible health. This includes not only treatment in time of sickness but health supervision in order to motivate people to seek this preventive care. Each physician must keep up-to-date in the newer developments in the medical sciences so as to afford his patient the best possible care.

PUBLIC HEALTH PROGRESS

Similar to the family physician for the patient, we have the family physician for the community, namely the health officer. The health department, comprised of public health physicians, public health nurses, sanitary engineers, and others, attempts to provide services to the community that cannot be provided by the family physician. States and localities have broadly defined public health as the protection and advancement of community health or, as defined by the Massachusetts law, "The Department (of Public Health) shall take cognizance of the interest of health and life among the citizens of the Commonwealth." [1] The provision of health services is not the perogative of the private practitioner or of the health department. It is everybody's business, and since there are certain essential and desirable services that people cannot provide for themselves or obtain from their physician, each state and territory and most localities have a health department. Over the past decade there has been a gradual coverage of the United States with local health departments, so that now approximately 75% of the population is covered by such service.[2]

Traditionally, health departments have sought to reduce or remove the major day-to-day threats to health. Originally charged with the responsibility for control of epidemics and sanitation, health departments have grad-

Read before the joint meeting of the Section on Pediatrics, the Section on Physical Medicine and Rehabilitation and the Section on Preventive and Industrial Medicine and Public Health at the 102nd Annual Session of the American Medical Association, New Yark, June 4, 1953.

Dr. Getting was formerly Commissioner of the Massachusetts Department of Public Health and is now at the School of Public Health, University of Michigan.

[1] Section 5, Chapter 3, of the General Laws, Commonwealth of Massachusetts.

[2] Emerson, H.: Public Health and Medical Care for the Community and the Individual, J. A. M. A. 148:41-44 (Jan. 5) 1952.

ually enlarged the scope of their activities as community problems have developed. As infectious diseases such as tuberculosis, syphilis, typhoid, and diphtheria became less prevalent owing to the joint endeavor of medical and public health professions, health departments became concerned with the improvement of maternal and child health and the special problems of the newborn. Now with the lengthening life span of the population, health departments are becoming more concerned with the health of the adult population and with chronic diseases. These are heart disease, cancer, diabetes, and others, diseases that today are the major causes of death in the U. S.[3] Prevention of home accidents and promotion of health through community education are more recent programs of health departments.

Public health programs, like the private practice of medicine, have been modified with the changing needs of the people and with new developments. New problems and techniques require new methods of organization. The distribution of gamma globulin for the prevention or modification of poliomyelitis is an excellent example of how the public health department, voluntary health organizations, and private practitioners of medicine can cooperate to bring benefits to the people. It is as unrealistic to attempt to solve today's health problems by the methods developed 50 years ago as it is for the physician to attempt to practice modern medicine without the use of antiseptics, modern anesthetics, sulphonamides, antibiotics, cortisone, or antihistamines. Constant changes are necessary to adapt public health programs to changing conditions.

Unfortunately, in some areas of the country private practitioners regard with suspicion any new developments in public health programs. As hearty individualists, physicians are naturally reluctant to change their mode of practice or living and to depart from previously well-worn routines; and yet most changes are just as new and disturbing to health department personnel as they are to the private practitioner. But, with the demands of the public for improved services, both the private physician and the health officer must adapt themselves to changes as quickly as possible, with the knowledge that they are thus able to give better service.

REFERRALS FROM HEALTH DEPARTMENT

Health departments have traditionally worked with the full cooperation of the medical profession. The family physician is the front line of any public health endeavor. In order for a community health program to succeed the practitioner must give full cooperation and active rather than passive support. Experience has shown that the more extensive the public health program a community enjoys, the greater the demand made by the public on services not only for the treatment of illness but also for health supervision and for preventive services.

Health departments often refer patients to the private physician. As far back as 1933, Anderson and Bigelow[4] in a study of diphtheria immunization in Massachusetts found that such a program created an unusual demand for private service from the family physician, even though free service was available in public clinics. This experience can be cited repeatedly. Over 11 years ago, while Commissioner of Public Health for the city of Worcester, Mass., I was responsible for writing and delivering a weekly radio broadcast on health. One of the objectives was the promotion of whooping cough immunization. As yet pertussis vaccine was not distributed by the health department nor was it given in the clinics. This promotional program was, therefore, designed with only one objective, namely, the referral of all children under 2 years old to their family physician for such treatment. The success of the immunization program by the private practitioner was measured by a rapid increase in the sale of pertussis vaccine. The immunization program of many cities and states illustrates this same experience today. While health departments promote immunization of children with the triple antigen, and while many children may be immunized in public clinics, it has been found that more and more parents take their children to the family physician for this service. This is invariably encouraged by the health department.

Another public health activity that refers many patients to the family physician is the school health program. In Massachusetts, New York, Illinois, and many other states, school children are required to be examined by a physician at periodic intervals. These examinations may be carried out by the school physician at the request of the parents whenever they do not obtain such services from their own physician. Children who need medical attention are referred to the family physician for diagnosis and care. The number of children given this required physical examination by a family physician has continually increased. Many schools have a special form that children are given to take to their parents urging the latter to seek the services of the family physician. The American Academy of Pediatrics has found that only 3% of the total volume of medical care to children is furnished in public clinics; thus 97% of such care must be given by the private practitioners of medicine.[5]

The development of screening programs designed to detect early cases of tuberculosis, diabetes, syphilis, cancer, heart diseases, and other physical defects has been an outgrowth of the simple x-ray screening programs for detection of tuberculosis. These programs are designed to detect in apparently well persons conditions that require the attention of the physician for diagnosis and treatment. The American Medical Association in the past has promoted a program for the annual physical examination of all adults. The impracticability of such a program must be apparent to all, since there are not enough physicians to make all the necessary examinations. The health department through the screening program, therefore, attempts to bring to the family physician's office persons with conditions requiring attention. Screening programs have been developed in many areas of the country, and the number of persons referred to private practitioners can be measured in the hundreds of thousands. Most of these have been for suspected tuberculosis. More recently, the multiple screening program of Richmond, Va., referred 12,000 patients to their physicians for examination and treatment. In Atlanta, Ga., 236,000 and in Alabama 356,000 persons were tested for tuberculosis, syphilis, and anemia.[6] In Massachusetts over 10,000 were screened for tuberculosis, syphilis, diabetes, anemia, vision and hearing defects, heart disease, and other conditions. Approximately 60% of these were referred to their physicians for diagnosis and treatment.[7] Similar multiple screening programs have been carried on in Indiana and in San Jose and San Francisco, Calif., and all have been for the purpose of referring persons with physical defects to their family physicians. A screening program is of no value unless the follow-up is made by the family physician or by a public clinic. Practically all, or over 97%, of the persons referred for follow-up in Massachusetts went to their own physicians for diagnosis and treatment. Thus these referrals by multiple screening programs foster patient-physician relationships.[8]

INCREASED PRACTICE

Many other programs have been administered by health agencies for the purpose of detecting early illness. Teachers and other school employees are given physical examinations and chest roentgenograms. Many of these examinations are carried out by private practitioners. Premarital blood testing is required by all the states except nine (Maryland, South Carolina, Mississippi, Arkansas, Minnesota, New Mexico, Arizona, Nevada, and Washington). Louisiana only requires the man to be examined. A prenatal blood test is required in all states except six (Tennessee, Alabama, Mississippi, Minnesota, Wisconsin, and Maryland). Many states require that each hospital inpatient and certain licensees, such as barbers and hairdressers, have a serologic test. The well child conference is designed to service persons who cannot obtain health supervision from the family physician; however, all infants requiring medical care are referred to a private physician. The establishment of well child conferences in a community often stimulates parents to seek similar health supervision from either a pediatrician or the family physician.

Many services are offered by health departments to assist physicians in the care of their patients: the provision of diagnostic laboratory aids; the free distribution of biologics for diagnosis, prevention, and treatment of communicable diseases; the availability of consultants and consultation clinics; and the provision of tumor diagnostic services. The health department thus assists the physician in providing high quality medical care without interfering in any way with the patient-physician relationship.[9]

Perhaps the most important health department program that brings patients into the physician's office is health education. This program has been greatly enlarged by participation of not only the medical profession through its national, state, and local medical societies and its specialty groups but also the voluntary health associations and the public press as well. Unfortunately, popular periodicals are sometimes guilty of presenting the melodramatic and the unusual, thereby giving the public information that is either misleading or incorrect. Because of daily exposure to health education, the American public is more health conscious and is demanding and expending more for health than ever in the history of the country.

Over the past two decades approximately 4.3% of the total consumer expenditure has been for medical care. In 1951 over 13.5 billion dollars was spent for medical care, including the services of physicians, dentists, nurses, and other practitioners, as well as hospital care, drugs, and appliances. Nearly two-thirds of these expenditures were paid directly by the consumer, about one-fourth by governmental agencies, and the remainder by philanthropy and industry.[10] The American public wants good health and is willing to pay for it.

SUMMARY AND CONCLUSIONS

Health is everybody's business. Optimal health is not an inalienable right and privilige of the individual that comes automatically. The health of the individual must be actively worked for, and the health of the community must be carefully planned, developed, and nurtured. The health program must consider the entire community. The keystone of every public health endeavor must always be the private practitioner of medicine, who must rely on the local health department for assistance. If the health department is properly organized and carries out the objective for which it was designed, it will support and improve the private practice of medicine. If the local health department is poorly organized, the health officer is poorly trained or engaged on only a part-time basis, or if the health department is inadequately financed and staffed, then the community health program will suffer, and the people will not demand medical care of high quality. As a result of this lack of motivation of the public to seek medical care the private practitioner is often denied the privilege of providing preventive measures, periodic health appraisals, and early care. The private practitioner of medicine gains the greatest satisfaction from his work when he can detect early such diseases as diabetes or cancer, institute the necessary diagnostic measures to arrive at a definite diagnosis, and see that his patient receives the necessary care, including rehabilitation.

In this presentation I have attempted to illustrate how the health department can assist the private practitioner and how an active health department can bring about a greater demand on the part of the public for many services from the physician. The development of health programs should, therefore, not be looked upon with suspicion by the private practitioner. The physician should be included in the development of all programs, and the medical society should be fully informed of the purposes and objectives of any particular program. In this way the physician has an opportunity to participate in the formation of new public health programs, which he should then accept cheerfully. Such programs send him patients who require attention and patients in the early stages of disease to whom he can be of greater service. Unfortunately, many physicians do not attend medical society meetings, nor do they read, with any great regularity, information sent to them by the health department or appearing in various publications. Thus, often physicians may not be aware of the true purposes and objectives of new public health programs, and, since they lack knowledge, they oppose instinctively.

Physicians have an obligation not only to their own patients but to the community as a whole. The practice of medicine includes not only the physician's responsibility to his patient and the patient's family but also his responsibility in the planning, development, and enactment of public health programs. A family physician who ignores or who, because of lack of information, passively resists public health measures is being of disservice to his own patients, to himself, and to his profession.

The future of American medicine will depend more and more on individual action of the people. Many physicians are first learning of new scientific developments not in medical journals but from patients who have learned of these developments from television, radio, or the press. Working together, the medical profession and the health department can assure the private practitioner a position in which he can offer his patients the best medical care available. His rewards for such community participation are increased professional satisfaction and increased motivation of the public to seek adequate medical care.

NEW CHOLINERGIC DRUGS FOR POSTOPERATIVE URINARY RETENTION

Mandel Weinstein, M.D.,
and
Morton Roberts, M.D., Jackson Heights, N. Y.

Postoperative urinary retention, in the absence of primary organic disturbances in the urinary bladder, may ensue as a sequel to surgical operations notwithstanding a full bladder, normal kidney function, and the desire to void. To counteract this condition, new cholinergic drugs have been developed that increase the vesical activity and mimic the effects of parasympathetic stimulation.[1] Clinically, they have been shown to produce increased bladder activity and thus aid in the promotion of normal urinary function.[2]

In the following report the effectiveness of two new members of this cholinergic group, benzpyrinium (Stigmonene) bromide [1-benzyl-3-(dimethylcarbamyloxy) pyridinium bromide] and 1,2-xylylene-bis[1-(3-dimethylcarbamyloxy)-pyridinium bromide], a related experimental cholinergic compound coded W341, are compared and their efficacy evaluated in the treatment of established postoperative urinary retention. The chemical configuration of the two cholinergic compounds are given in figure 1.

That benzpyrinium bromide acts as an inhibitor of cholinesterase,[3] is less toxic than physostigmine or its derivatives, and is clinically devoid of side-effects in therapeutic doses, are facts that have been demonstrated by many clinical investigators.[4] Comparative pharmacological studies established that compound W341 is, in all particulars, a more active cholinergic than benzpyrinium bromide.

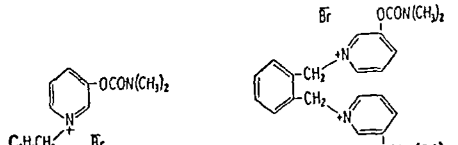

Fig. 1.—Chemical configurations of benzpyrinium bromide (on the left) and compound W341 (on the right).

CLINICAL MATERIAL AND PROCEDURE

Of 1,948 surgical procedures, urinary retention developed in a total of 160 patients. Our study is based on observations made on this group. History and physical examination precluded patients who had urinary disease. The operative procedures were laparotomies of major character in almost all instances. The type of anesthesia and preoperative and postoperative medication were evaluated as to the part each may have contributed to the vesical atonia. Eighty-six of the patients were males. The ages ranged from 12 to 77 years. Postoperative urinary retention was deemed to be established if a patient could not empty the bladder voluntarily within about 11 to 12 hours after the surgical procedure. This impression was confirmed by palpation, percussion, and the clinical picture at that particular moment. To stimulate voiding he was helped not only by sympathetic and persistent nursing care but also by early ambulation,

which makes it possible for the patient to assume the most natural posture conducive to voiding. At this point, an intramuscular injection of the drug or placebo was administered and repeated every two hours until satisfactory micturition occurred or catheterization became necessary. In the latter instance therapy was continued until the patient voided spontaneously.

A preliminary appraisal of benzpyrinium bromide in the treatment of established urinary retention resulting from atony of the bladder disclosed, however, that the recommended dosage of 1 cc. of a 1:2,000 solution (0.5 mg.) every three hours to a total of five doses was not productive of the desired effect. Since Cohen and coworkers demonstrated clinically the wide therapeutic dosage range of benzpyrinium bromide, it was felt, firstly, that a higher dosage could be employed without ill-effects and, secondly, in so doing the optimal dosage could be established. Furthermore, it was believed that if there was an appreciable difference in the results obtained employing two different doses of the same drug under identical conditions, the use of a true placebo for control purposes would not be essential to the evaluation.

Accordingly, then, in this investigation 40 of the 160 patients received intramuscular injections of a 1:1,000 solution (1 mg.) of benzpyrinium bromide every two hours until the bladder was satisfactorily emptied or catheterization became necessary. A second group of 40 patients received intramuscular injections of 1 cc. of a 1:500 solution (2 mg.) of benzpyrinium bromide at two hour intervals.

Of the remaining 80 patients, 40 received intramuscular injections of a placebo for control purposes and 40 intramuscular injections of 1 cc. of a 1:1,000 (1 mg.) solution of compound W341. The conditions under which compound W341 and the placebo were administered were as identical as possible with those of the two groups that received benzpyrinium bromide.

RESULTS

Series 1.—The results obtained in the series of 80 patients who were treated with intramuscularly administered benzpyrinium bromide, 1 mg. and 2 mg., respectively, are summarized in table 1. Of 40 postoperative patients with established urinary retention, 24, or 60%, were able to empty their bladders satisfactorily when 1 mg. of benzpyrinium bromide was given every two hours. In the remaining 16 patients, who had to be catheterized, the catheter was used 21 times. Voiding without difficulty was effected on an average of 7½ hours after initiation of the drug therapy. The average number of injections was 4.2. In the group of 40 patients in similar circumstances who received 2 mg. of benzpyrinium bromide intramuscularly, 37, or 92.5%, voided with good emptying of the bladder. It was necessary to catheterize three patients only once in each instance. Normal bladder function was reestablished on an average of 4¼ hours after the first dose of benzpyrinium bromide was given. The average number of injections administered was 2.8.

When the results were compared in these two groups of 40 patients each, it was found that when the 2 mg. dose of benzpyrinium bromide had been administered intramuscularly every two hours, the incidence of necessary catheterization was reduced 32.5%. In addition, it should be noted here that the catheter had to be used only three times in the group receiving the 2 mg. dose, while those on the 1 mg. dose required the catheter on 21 occasions. Moreover, on the average, satisfactory micturition was initiated within just a little more than half the time required with the 1 mg. dose. When it is considered that the psychogenic factor was of similar magnitude in both groups, it would appear that in the treatment of established postoperative urinary retention optimal results may be produced with the administration of 2 mg. doses of benzpyrinium bromide. No toxic manifestations or side-effects were observed following injections of either 1 mg. or 2 mg. doses of benzpyrinium bromide.

Series 2.—A summarization of the results achieved in the remaining series of 80 patients with established urinary retention is presented in table 2. As in the cases of series 1, the postoperative complication of an atonic bladder developed as a sequel to similar surgical procedures; therapy was instituted and executed in like manner. Of the 40 control patients with diagnosed bladder atonia who were given intramuscular injections of a placebo every two hours, 29, or 72.5%, emptied their bladders by spontaneous voiding. Eleven had to be catheterized a total of 35 times. On an average, normal micturition in this control group occurred 12 hours after the first dose of the placebo was administered. This response occurred after 6.4 injections. The remaining 40 patients of this series were treated with compound W341 administered intramuscularly. Receiving 1 mg. every two hours, 36, or 90%, were able to expel the contents of their full bladders. Only four patients had to be catheterized, requiring a total of 10 catheterizations. Normal micturition was restored on an average of 5¼ hours after the initiation of compound W341 therapy, necessitating 3.6 injections.

in the formation of new public health programs, which he should then accept cheerfully. Such programs send him patients who require attention and patients in the early stages of disease to whom he can be of greater service. Unfortunately, many physicians do not attend medical society meetings, nor do they read, with any great regularity, information sent to them by the health department or appearing in various publications. Thus, often physicians may not be aware of the true purposes and objectives of new public health programs, and, since they lack knowledge, they oppose instinctively.

Physicians have an obligation not only to their own patients but to the community as a whole. Intestinal resection, and release of obstruction and adhesions	..	..	..		2	2	..	
Laparotomy (exploratory)	1	1	..		..	..	..	
Vein ligation	1	..	1	(2)	..	..	..	
Total	40	24	16	(21)	40	37	3	(3)
Male	24	14	10		22	20	2	
Female	16	10	6		18	17	1	

Series 2.—A summarization of the results achieved in the remaining series of 80 patients with established urinary retention is presented in table 2. As in the cases of series 1, the postoperative complication of an atonic bladder developed as a sequel to similar surgical procedures; therapy was instituted and executed in like manner. Of the 40 control patients with diagnosed bladder atonia who were given intramuscular injections of a placebo every two hours, 29, or 72.5%, emptied their bladders by spontaneous voiding. Eleven had to be catheterized a total of 35 times. On an average, normal micturition in this control group occurred 12 hours after the first dose of the placebo was administered. This response occurred after 6.4 injections. The remaining 40 patients of this series were treated with compound W341 administered intramuscularly. Receiving 1 mg. every two hours, 36, or 90%, were able to expel the contents of their full bladders. Only four patients had to be catheterized, requiring a total of 10 catheterizations. Normal micturition was restored on an average of 5¼ hours after the initiation of compound W341 therapy, necessitating 3.6 injections.

A comparison of the results produced with compound W341 and a placebo in these two groups of 40 patients each reveals, firstly, that when the 1 mg. dose of compound W341 was given intramuscularly every two hours the incidence of necessary catheterization was reduced 17.5%, secondly, a drop of 28.6% in the individual use of the catheter was effected, and, thirdly, on the average, normal micturition was reestablished in considerably less than one-half the time required with the placebo. Since there should be no reason to differentiate between the psychogenic factors involved in those patients receiving compound W341 and those getting the placebo, it may be concluded that the 1 mg. dose of compound W341 was singularly effective in relieving the postoperative bladder atony. Compound W341 was well tolerated. In one instance only, after the 12th dose, was a side-reaction, diarrhea, observed.

Table 2.—*Results in Cases of Established Urinary Retention Utilizing Cholinergic Compound W341 and Placebo*

COMMENT

A graphic illustration of the results obtained in this investigation of a total of 160 patients with established postoperative urinary retention is presented in figure 2. On examination, it will be found that the 2 mg. dose of benzpyrinium and the 1 mg. dose of the cholinergic compound W341 manifest very high therapeutic effectiveness. With respect to the former, this finding parallels that of Cohen and co-workers and of Decker. However, when a comparison is made between the results produced with the 1 mg. dose of benzpyrinium and the placebo it becomes apparent that, unexpectedly, fewer patients receiving the placebo had to be catheterized. Yet, as anticipated, these patients required individually and collectively the largest number of catheterizations to restore normal micturition. Inasmuch as it was endeavored to maintain uniform conditions throughout the study, it is difficult to evaluate the factors responsible for this incongruity. One that might have a bearing on the results is that in the group receiving the 1 mg. dose of benzpyrinium there were about twice as many appendectomies and gastrectomies as in the group that received the placebo. These operative procedures on the bowel and stomach may or may not be significant. The figures in table 3 indicate that the average incidence of postoperative urinary retention is 8.3%, no matter what type of surgical maneuver is performed; however, it will be noted that with operations on the pelvic viscera, e. g., total hysterectomy, or in the inguinal region, the incidence rises to about 10%.

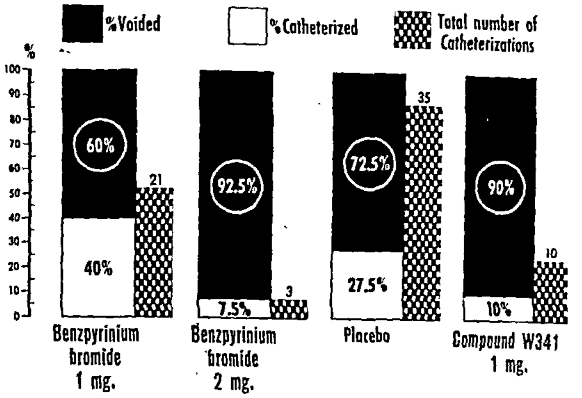

Fig. 2.—Comparative results in cases of established urinary retention with benzpyrinium and W341.

Following rectal surgery the incidence of urinary retention is more than twice that following laparotomies. This might be a reflection of the close association between the nerve supply of the bladder and rectum via the inferior hypogastric and pelvic plexuses. It is possible that trauma to this innervation during the operation causes vesical dysfunction.

Gastric operations contributed the highest percentage of cases with bladder atonia. One of many factors involved in the relatively high incidence of this complication may be the use of comparatively large amount (2 to 3 gm.) of thiopental (Pentothal) sodium for supplemental anesthesia in these gastrectomies. The average amount of thiopental sodium used for all other operations in this study is usually about 0.5 gm. or slightly higher.

Table 3.—*Incidence of Postoperative Urinary Retention*

Type of Operation	No. of Cases	Cases of Urinary Retention	Percentage of Urinary Retention
Appendectomy	620	32	5.2
Cholecystectomy	203	15	7.4
Gastrectomy	124	22	17.7
Hemorrhoidectomy, fissure, pilonidal cyst, and rectal amputation	150	24	16.0
Herniorrhaphy	347	34	9.8
Hysterectomy	180	17	9.4
Intestinal resection	58	3	5.2
Laparotomy, salpingectomy, oophorectomy, and nephrectomy	138	8	5.8
Mastectomy	42	3	7.1
Vein ligation	71	1	1.4
Skin graft	15	1	6.7
	1,948	160	Average 8.3

SUMMARY AND CONCLUSIONS

Benzpyrinium (Stigmonene) bromide and the experimental cholinergic compound W341 are clinically evaluated in a total of 160 patients with established postoperative urinary retention. In the absence of urinary tract disease the 2 mg. dose of benzpyrinium bromide as well as the 1 mg. dose of the cholinergic compound W341 has been found to considerably shorten the duration of vesical atonia, thus reducing markedly the necessity for catheterization and/or the number of individual catheterizations. Episodes of toxicity have not been encountered with the administration of either the 1 mg. or 2 mg. dose of benzpyrinium bromide or the 1 mg. dose of compound W341. Both compounds were found to be effective but gentle in action and safe for both old and young patients.

75-17 41st Ave. (Dr. Weinstein).

OFFICE USE OF THE FROG TEST FOR PREGNANCY

Jane E. Hodgson, M.D., St. Paul

The use of the male frog for the determination of pregnancy has been described and discussed frequently during the past four years. Most of the articles concerning the test have been written by pathologists or persons engaged in institutional work or research. Only a few reports have been made by clinicians who engage in obstetric practice and who perform this pregnancy test in their own offices. As a clinician engaged in the practice of obstetrics and gynecology, I wish to report on my experiences with the Rana pipiens test during the past three years. In that time, a total of 450 pregnancy tests were performed in my office on 350 urine and 100 serum samples.

The Rana pipiens test for pregnancy is based on the release of sperm in the urinary bladder of male frogs after they have been injected with an adequate amount of chorionic gonadotropin. This amount is approximately 1 I. U. per gram of frog. Chorionic gonadotropin appears in the serum and urine of pregnant women between the 22nd and the 25th cycle day. A positive frog test may result as early as the 30th cycle day. Most urine or serum of a pregnant woman produces a positive reaction by the 35th cycle day. Our earliest positive responses were obtained on the 34th cycle day.

PROCEDURE

Adult male frogs are maintained in a covered enamel pan in a biological refrigerator and kept at a temperature between 0 and 10 C. At this temperature, the frogs remain in a state of hibernation and require no food or attention. The bottom of the pan is covered with fresh water that is changed daily. Few frogs die, and most of them remain in a healthy state for months at a time. The sex of the frog should be carefully noted. The male is distinguished by large pigmented thumbs, inflated air sacs, and the ability to croak.

Weighing the Frogs.—We determine the amount of urine or serum to be injected on the basis of the frog's weight. To our knowledge no laboratory has heretofore weighed the frogs to determine the amount of urine or serum to be injected. Several writers have pointed out the higher sensitivity of the smaller frogs when a fixed amount of chorionic gonadotropin was injected. It would seem logical, therefore, to adjust the dosage according to the frog's weight, which may range from 20 to 60 gm. Our dosage schedule is 1 cc. of urine or serum for each 10 gm. of frog. When urine concentrate is used, 1 cc. of the concentrate is injected for every 15 gm. of frog.

Preliminary Study of Frog's Urine.—After the frog is weighed, he is placed in a clean, dry jar with a perforated cover to thaw out for a brief period. The frog's urine is routinely checked prior to injection of the patient's urine or serum in order to assure absence of sperm. A frog usually can be made to void if its thighs are flexed and it is pressed down on a glass slide. Urine can also be obtained from the frog by inserting a capillary pipet into the cloaca. The urine is examined on a glass slide under a microscope to make certain that there are no sperm in the urine that will give false positive reactions.

Injection of Human Urine.—Fasting morning urine is used. The specific gravity should be at least 1.010, and filtration is advisable. The necessary amount of urine (1 cc. per 10 gm. of frog) is injected into one frog. The injection may be either intraperitoneal or in the dorsal lymph sac; care should be taken to avoid leakage of urine back through the hole made by the hypodermic needle. The frog is then put back in the jar. From 30 minutes to three hours later, the frog's urine is obtained and examined for sperm. A positive response may appear between 30 to 50 minutes after injection. If no sperm are demonstrated within three hours, it is necessary to confirm this negative response by concentrating the urine and injecting it into two other frogs. Scott's kaolin adsorption method is used.[1] By this method, 1 cc. of urine concentrate contains chorionic gonadotropin equivalent to that in 20 cc. of urine. This method of concentration is a relatively simple procedure that can be performed by any qualified laboratory technician in approximately 30 minutes. The resulting solution is injected into two frogs, both of which have been checked as to sex, weight, and absence of sperm in the urine; 1 cc. of the concentrate is injected for each 15 gm. of frog. The injection of two frogs eliminates the possibility of a false negative reaction that might result from a lack of individual reaction in one animal. If, in three hours, there are no sperm demonstrable from either frog, the negative response is accepted. If either frog shows a positive response, the test is considered positive. If less than two weeks have elapsed since the patient's last period (if it is less than the

42nd cycle day), all negative tests should be repeated in one week. Also, if a history of menstrual irregularity precludes the accurate determination of the cycle day, it is advisable to recheck negative responses in one week.

Injection of Human Serum.—Unoxalated blood, 20 cc., is centrifuged, and the resultant serum is injected into each of two frogs; 1 cc. for each 10 gm. of frog. Injections are intraperitoneal. The frog's urine is examined for sperm between 30 minutes and three hours after injection. A positive response in either frog constitutes a positive test for pregnancy. If neither frog responds, the negative response is accepted and the test is completed unless it is performed prior to the 42nd cycle day. In such an event, it is advisable to repeat the test in one week.

MODIFICATIONS OF PROCEDURE

At first, we attempted to test random urine samples from patients who were being seen in the office throughout the day. The frog mortality rate was high with the random use of urine, however, and it became apparent that the fasting morning specimens were far more satisfactory. Moreover, it is evident that the latter contains a higher concentration of chorionic gonadotropin.

By weighing the frogs to determine the amount of serum or urine to be injected, we feel that we have improved the consistency of our result and that each frog is injected with the maximum amount of urine or serum that it will tolerate. The importance of the use of duplicate frogs is self-evident.

The initial examination of the frog's urine to exclude the presence of sperm prior to injection of human urine or serum may eliminate an occasional false positive reaction. While the male frog does not release sperm in the urine under ordinary laboratory conditions, it is possible that recent capture or excessive handling cause the presence of sperm prior to injection of the chorionic gonadotropin; therefore, all of our frogs are checked initially in this regard. Since instituting this procedure in our last 150 tests, we have found sperm at the time of the initial urine examination on three occasions.

When a negative response is obtained with fasting morning urine, two additional frogs are injected with urine concentrate. In the series of 350 tests of urine samples, this routine has prevented 20 false negative responses.

We do not accept a negative response prior to the 42nd cycle day. This rule has applied to the use of either urine or serum. In our 450 tests, however, we have avoided only five false negative responses by following this rule, inasmuch as most urine and serum samples cause a positive response by the 35th cycle day.

PATHOLOGICAL PREGNANCIES

Our series includes three cases of hydatidiform moles. In the most outstanding case, diagnosis was established at three months, by the fact that a positive frog test was obtained from a urine dilution of 1:700. In no instance of threatened abortion in patients in whom we tested urine and serum did the pregnancy continue after a negative response to the frog test was obtained. In many, however, the response was positive on the day the abortion occurred, and in one of these the response was still positive the day after delivery of secundal tissue.

There seems to be a definite relationship between the number of sperm released and the amount of chorionic gonadotropin injected. Some authors have stated that there are no intergrades of response in this reaction. In very early pregnancy, in abortion patients, and in instances in which unconcentrated urine containing little chorionic gonadotropin is used, the number of sperm is definitely fewer. We repeated as many as seven tests on one patient undergoing an abortion and noted a gradual diminution in response corresponding to the separation of chorionic villi. During very early pregnancy, urine frequently produces only a few sperm. Repetition of the test a few days later usually shows a marked increase in sperm response. There is also a definite time-dose relationship that has already been pointed out by Haskin and Sherman.[2] The urine from one of our patients with a hydatidiform mole showed a markedly positive response after only 10 minutes. On diluting the urine up to 1:700, the time required for a positive response lengthened and the number of sperm diminished.

RESULTS WITH URINE SPECIMENS

In 350 urine tests, there were 202 correct positive responses. There were 20 negative responses with unconcentrated urine, but, when the urine concentrate was injected, the response became positive. An additional two responses were negative prior to the 42nd cycle day, but correctly positive when repeated one week later.

There were 137 correct negative responses in the series. There was one false negative response on the 56th cycle day. A positive response was obtained on the 64th cycle day.

There were four false positive responses in this series, details of which are of interest. A 22-year-old unmarried woman with a large uterine fibroid was tested prior to surgery. A weak positive response was obtained with one frog on the injection of the urine concentrate. A second test two days later was negative with two frogs. In a 28-year-old woman who had been sterile for six years and who had amenorrhea, concentrated urine gave a weak positive response. In a 44-year-old woman with amenorrhea, concentrated urine gave a positive response with one frog only. A repeat test elicited a weak positive response in only one of two frogs. In a 52-year-old woman a weak positive response was elicited in only one of two frogs. A repeat test was negative.

In addition, there were two patients whose urine concentrate elicited a weak positive response a few weeks after abortion. Whether these two represented false positive responses, a slow falling chorionic gonadotropin titer remaining from the previous pregnancy, or a new pregnancy that later terminated in abortion, it is impossible to state.

There were four other cases in which strong positive responses were elicited with unconcentrated urine but in which pregnancy could not be proved. In these four cases, however, there was a possibility of mixed specimens and inaccurate histories and follow-ups, and we have, therefore, classified them as possible false positive responses.

---

[2] Haskins, A. L., Jr., and Sherman, A. I.: Quantitative Bio-Assay of Chorionic Gonadotropin with the Male Frog, Endocrinology 44: 542, 1949.

It is of interest to note that all of the definitely false positive results were obtained with urine concentrate. Several authors have suggested that an excessive amount of urine equivalent might produce false positive reactions. This theory may explain the fact that we had no false positive reactions or even possible false positive reactions in 100 serum tests.

RESULTS OF SERUM TESTS

During the past 12 months, the use of serum instead of urine has been proved distinctly advantageous. The serum specimens can be obtained at any time along with routine blood studies and even without the patient's knowledge. In 100 consecutive serum tests, as stated previously, we had no false positive results and only one possible false negative response.

In the 100 consecutive serum tests, there were 54 correct positive responses and 39 correct negative responses. There were six pathological pregnancies that cannot rightfully be classified as false negative responses. One patient had an ovarian pregnancy, and five aborted; in these five, the responses were all negative except one. In one patient, the serum gave a negative response on the 38th cycle day. Six days later on the 44th cycle day, the patient aborted a pathological ovum. In another patient, there was a negative response on the 60th cycle day. A repeat test on the 78th cycle day was positive. The patient, however, aborted on the 79th cycle day. A negative response was obtained on the 60th cycle day in a 43-year-old woman. Ten days later, she spontaneously aborted necrotic placental tissue. A negative response was obtained on the 51st cycle day in a 27-year-old woman; she aborted the same day. A negative response was obtained on the 50th and 72nd cycle days after a dilatation and curettage. A weak positive response (one frog only) was obtained on the 101st day; the patient aborted on that day.

This series of 100 serum tests was performed between April, 1952, and April, 1953. This includes the summer months during which a number of writers have reported a high incidence of false negatives because of the apparent unreliability of the frogs during warm weather. Our high accuracy during the summer months as compared to that of others may be the result of cool climate, proximity to the source of frogs, shipment of frogs by air, refrigeration of frogs, higher concentration of chorionic gonadotropin in serum as compared to that found in urine,[3] and weighing the frogs to determine the dosage. This latter factor is probably more important in the summer months when there seems to be a greater variation in the size of the frogs (from 20 to 60 gm.). We have demonstrated that 60 gm. frogs fail to give a positive response to the same amount of chorionic gonadotropin hormone that produces the release of sperm in a 20 to 30 gm. frog.

The advantages of the use of serum as compared to fasting morning urine are self-evident. They are (1) decreased toxicity of serum to the frog, (2) elimination of the urine concentration procedure with all negative responses, (3) ability to perform test at any time, (4) less opportunity for substitution of specimens, and (5) elimination of transportation of urine to laboratory. We still perform pregnancy tests with urine specimens when this is more convenient.

ACCURACY AND USEFULNESS

The accuracy of the frog test has been reported as ranging from 54 to 99%. The methods of performing the test are as varied as the results. It is noted in many articles that unconcentrated urine was used in small amounts and that the frogs were not refrigerated and were used more than once. Inasmuch as this is a test for the presence of a chorionic gonadotropin in the urine, the incidence of false negative responses will be higher in those laboratories in which the urine is unconcentrated, frogs are unhealthy, small amounts of urine are injected, and negative responses are accepted in the very earliest days of pregnancy. Analyses of various authors' results should receive the closest scrutiny. It is extremely important to know what percentage of their tests were performed on pathological pregnancies. Nearly everyone agrees on the infrequency of false positive reactions, but there is considerable difference of opinion on the frequency of false negative responses. Unless a physician is familiar with each patient and her subsequent clinical course, it is impossible to evaluate accurately the results and validity of each test. For example, in a woman who presents a clinical history and impression of pregnancy, the response to the frog test may be negative; spontaneous abortion occurs 12 hours after the test is performed. Is this to be classified as a false negative response? Our series includes nine pathological pregnancies in which the level of chorionic gonadotropin was apparently too low to elicit a positive response before the spontaneous abortion occurred. Ectopic pregnancies show positive pregnancy tests only about half of the time, no matter which type of test is used. Furthermore, in any large series, there are always several possible early pregnancies and abortions that defy even the pathologist in the establishment of an absolute diagnosis. It is my feeling that the accuracy of the frog test in normal pregnancies is at least 98%, provided that the routines previously described are strictly followed. In cases of pathological pregnancies, such as missed abortions, ectopic pregnancies, threatened abortions, and hydatidiform moles, the frog test is extremely helpful to the clinician in treatment and prognostication. Its speed and simplicity give it distinct advantages over other types of pregnancy tests in present use. If, in a woman who has shown clinical signs of pregnancy, response to the frog test is not positive after the 42nd cycle day, I would not hesitate to predict that the pregnancy is a pathological one that will have an unsuccessful outcome.

A number of obstetricians have stated that they performed so few pregnancy tests that they have no need for an office procedure and that although pregnancy tests are helpful in pathological cases, in the diagnosis of normal pregnancy, a waiting period of a few weeks is of no concern.

A woman today is often extremely anxious to receive a diagnosis of pregnancy as early as possible. She may have commitments pertaining to a job, housing problems, a husband in service, and numerous and adequate reasons far more important than the mere satisfaction of her curiosity. Patients demand an early diagnosis of pregnancy and are grateful for it. Since the test has been available to me in my office, the frequency with which I request it has multiplied many times, the service to the patients is greater, and, in cases of pathological pregnancy, medical care is of a higher standard. The frog test is also of value as a routine preoperative test. The most astute diagnostician will sometimes discover an early pregnancy at the time of laparotomy; routine preoperative frog tests would help eliminate this error.

---

[3] Smith, R. A.; Albert, A., and Randall, L. M.: Chorionic Gonadotropin in the Blood and Urine During Early Pregnancy, Am. J. Obst. & Gynec. 61: 514, 1951.

CONCLUSIONS

The frog test, with either serum or urine, for pregnancy is recommended as a routine office procedure. The use of serum is much simplier and apparently equally or more accurate. Seasonal variations in frog reactivity has proved to be no handicap if strict adherence to the routine procedures outlined is maintained. On the basis of the results of the 450 tests reported, I believe the accuracy of the frog test, in normal pregnancies, is at least 98%. In instances of pathological pregnancies, the result of the frog test is helpful in determining prognosis and instituting treatment.

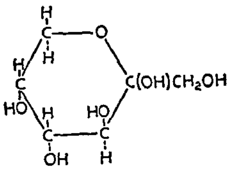
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Fructose.—Levugen (Mead Johnson).—$C_6H_{12}O_6$.—M.W. 180.16. —Levulose.—Fructose is prepared by the inversion of aqueous solution of sucrose and subsequent separation of fructose from glucose. The structural formula of fructose may be represented as follows:



Actions and Uses.—Fructose (levulose) like dextrose, administered intravenously in solution, is useful for parenteral carbohydrate alimentation when either fluid or calories are required to replace or supplement the oral consumption of water or food. Fructose is more rapidly metabolized and more rapidly converted to liver glycogen than is dextrose. When infused at comparable rates, it results in lower levels of blood sugar and less urinary spillage. Fructose is metabolized or converted to glycogen in the absence of insulin, but the clinical application of this has not been fully determined.

Fructose can be infused at the same rate as but in twice the concentration of dextrose, with better retention and less disturbance of fluid balance. Thus fructose can be employed safely to supply calories more rapidly than either dextrose or invert sugar (half dextrose and half fructose) and to provide more nearly the carbohydrate requirements of patients who need parenteral alimentation. Although fructose is not toxic, excessively rapid intravenous infusion is contraindicated as with other parenteral solutions.

Dosage.—Fructose is administered by intravenous infusion as a 10% solution in water. It can be administered at the same rate as a 5% solution of dextrose. The total daily amount required varies with the patient. For adults the usual initial dose is 1 liter; the average dose, 2 liters; and the maximum dose, 3 liters. For children the total daily amount is determined on the basis of the size and total blood volume of the child. In infants this usually ranges from 0.1 to 1 liter and in children from 0.2 to 2 liters. If administered in quantities in excess of the amounts indicated, any unutilized portion will be excreted in the urine.

Since fructose decomposes in alkaline solution, substances which would raise the pH to values above 7.0 should be added only if the solution is to be administered promptly. Compounds of calcium and barium form insoluble complexes when the pH exceeds 7.0 and are therefore incompatible. Cloudy solutions should not be used.

Tests and Standards.—

Dosage Forms of Fructose

Solutions. (10%) *Physical Properties:* The solution is clear and colorless. The specific gravity is 1.033-1.039, the refractive index is 1.346-1.348, and the pH is 3.0-3.5.

Identity Tests: To 5 ml. of hot alkaline cupric tartrate T.S. add a few drops of 10% fructose: a red precipitate of cuprous oxide appears *(presence of reducing sugars).*

Prepare a 0.05% solution of resorcinol in hydrochloric acid diluted 1:1. To 5 ml. of the solution add 1 ml. of 10% fructose and heat in a boiling water bath for 2 min.: a cherry-red color appears *(presence of ketohexose)*

Prepare a solution containing 1 gm. of phenylhydrazine hydrochloride and 1.5 gm. of sodium acetate in 10 ml. of water by heating the mixture to about 60°, cooling, and filtering. To 5 ml. of this solution in a test tube add 1.5 ml. of 10% fructose. Place the test tube in a boiling water bath for about 5 min. Crystals begin to appear in 2.0-2.5 min. Cool the reaction mixture, filter it, and wash the precipitate with three 10 ml. portions of water followed by single washings with 5 ml. of alcohol and 5 ml. of ether. Dry the residue at 105° for 30 min.: the yellow osazone formed melts at 205-210° (with decomposition).

The specific rotation, $[\alpha]25,\text{D}$, of 10% fructose is between —90.0 and —94.5°.

Purity Tests: To 10 ml. of 10% fructose add 1 ml. of ammonium oxalate T.S.: *the solution remains clear for 1 min. (absence of calcium).*

To 50 ml. of 10% fructose add 2 ml. of nitric acid and exactly 10 ml. of 0.02 *N* silver nitrate. Heat the mixture on a steam bath to coagulate the silver chloride, cool, and add 5 ml. of nitrobenzene and 2 ml. of ferric ammonium sulfate T.S. Titrate the excess silver nitrate with 0.02 *N* ammonium thiocyanate. Each milliliter of 0.02 *N* silver nitrate consumed is equivalent to 0.0007092 gm. of chloride: the amount of chloride does not exceed 0.025%.

Dilute 1 ml. of 10% fructose to 25 ml. with water, add 1 ml. of barium chloride T.S., shake, and allow the mixture to stand for 1 min.: the turbidity does not exceed that of 0.2 ml. of 0.02 *N* sulfuric acid diluted to 25 ml., and treated in the same manner *(presence of not more than 0.2% sulfate).*

Transfer to a test tube 10 ml. of 10% fructose. Add 5 ml. of ether and shake vigorously. Separate the layers, transfer 2 ml. of the *ether layer* to a test tube, and add 1 ml. of a 1% solution of resorcinol in hydrochloric acid: a slight pink color may form but no cherry-red color appears immediately *(absence of hydroxymethylfurfural).*

Transfer exactly 10 ml. of 10% fructose to a tared crucible and remove the water by evaporation on a steam bath. Char the residue, cool, add 1 ml. of concentrated sulfuric acid, and continue ignition until no carbon remains: the amount of residue does not exceed 0.5%. Save this residue for the heavy metals test.

To the residue from ashing add a mixture of 30 ml. of diluted hydrochloric acid and 3 ml. of bromine T.S., cover the crucible, and boil gently for 10 min. Filter, and wash the filter and residue with 25 ml. of hot water. Evaporate the filtrate to dryness, dissolve the residue in 15 ml. of water, add 2 ml. of diluted acetic acid, and dilute to 25 ml. with water. Prepare a standard with 0.5 ml. of U. S. P. standard lead solution, and treat it with the same quantities of the same reagents and in the same manner. Run a *U. S. P. heavy metals test:* the amount of heavy metals does not exceed 5 ppm.

Assay: (Fructose) Prepare a 0.4% solution of fructose and using 20 ml. of this solution assay for fructose as directed in *Official Methods of Analysis of the Association of Official Agricultural Chemists,* ed. 7, A.O.A.C., Washington, 1950, p. 508 and 512-513, par. 29.40, 29.41, 29.54, and 29.55. The amount of fructose is not less than 95.0 nor more than 105.0% of the labeled amount.

Mead Johnson & Company, Evansville, Ind.

Solution Levugen 10%: 1 liter bottles. A solution containing 0.1 gm. of fructose in each cubic centimeter.

APPROVED INTERNSHIPS AND RESIDENCIES IN THE UNITED STATES

ANNUAL REPORT OF INTERNSHIPS AND RESIDENCIES BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Edward H. Leveroos, M.D., and Warren R. Von Ehren

Annual Report

The Council on Medical Education and Hospitals presents in this 27th Annual Report, statistical data and other information on Council-approved internship and residency programs. In addition to the customary tables on the number of internships and residencies, there is a breakdown of internship stipends for nonfederal hospitals, a report on the study made by the Advisory Committee on Internships, and a brief discussion of the National Intern Matching Plan. As in previous years, lists of approved internships and residency programs follow the report. These lists are published in reprint form as the Directory of Approved Internships and Residencies.

The report is based on information submitted for the fiscal or calendar year by hospitals conducting approved training programs. The statistical tables include information on the number of internships and residencies as of Sept. 1, 1952. The data differ therefore, from those contained in the lists of approved services, since these relate to appointments for the year beginning July 1, 1954.

Approved programs are listed as follows: a section on internships based on the state and city in which the hospital is located as well as one based on the type of internship being offered, a section on residency programs by specialties, and a section recapitulating the programs for which each hospital is approved.

The geographical list of approved internships includes data on the type of hospital, bed capacity, annual admissions, autopsy percentage, and stipend, as well as information on the type and number of internships. For those hospitals participating in the official plan for intern appointments, as sponsored by the National Intern Matching Plan, Inc., a code designation is given to each program offered. The list of approved residencies as classified by specialties includes statistical data for that particular service in addition to the name of the chief of service, number of years for which the program is approved, and other pertinent information.

The publishing of this report and the lists of approved services is made possible through the helpful cooperation of the medical staffs and administrators of hospitals in which approved training programs are being conducted. The Council takes this opportunity to express its appreciation for the excellent support it has received from them, as well as for the valuable contribution of the administrative officers of medical schools and the federal services this year, as in the past. To the following organizations with which the Council collaborates in the approval and listing of residency programs, the Council wishes to make grateful acknowledgment:

Advisory Board for Medical Specialties
American Board of Anesthesiology
American Board of Dermatology and Syphilology
American Board of Internal Medicine
  Subspecialty Board on Allergy
  Subspecialty Board on Cardio-Vascular Diseases
  Subspecialty Board on Gastroenterology
  Subspecialty Board on Pulmonary Diseases
American Board of Neurological Surgery
American Board of Obstetrics-Gynecology
American Board of Orthopedic Surgery
American Board of Otolaryngology
American Board of Pathology
American Board of Pediatrics
American Board of Physical Medicine and Rehabilitation
American Board of Plastic Surgery
American Board of Preventive Medicine
American Board of Proctology
American Board of Psychiatry and Neurology
American Board of Radiology
American Board of Surgery
American Board of Urology
Board of Thoracic Surgery
American College of Physicians
American College of Surgeons

The Annual Report is published for the information of members of the medical profession, educators, hospital administrators, and others interested in graduate medical education. The Directory of Approved Internships and Residencies as reprinted from the following lists of approved services has been designated as an official directory by a number of federal and state governmental agencies. Inquiries regarding the report and the directory should be made to the Council on Medical Education and Hospitals.

Internships

For the first time in several years, the number of internships in approved hospitals has decreased from that of the year previous. Last year, 865 hospitals offered 11,467 internship appointments. This year, 856 hospitals indicated that they had 11,006 internship positions available for the year beginning July 1, 1953. While the decrease, 3.4%, was not great, it may indicate a leveling off of the inflationary trend which has occurred over the past 10 years. It can reasonably be anticipated however, that a further voluntary decrease of any sizeable proportion is unlikely in view of the continuing demand for hospital services and the utilization of intern staffs to supply part of those services. In considering the over-all problem of the shortage of interns, it is significant to note that, while the number of hospitals offering approved intern training has increased 12% during the past 10 years, from 760 hospitals to 856, the number of internships in those hospitals has risen 32%, from 8,180 to 11,006 (table 1).

INTERNSHIPS BY TYPE OF SERVICE

A breakdown of the number of internships filled and vacant by type of service is shown in table 2. The number of approved hospitals offering internships in each cate-of her curiosity. Patients demand an early diagnosis of pregnancy and are grateful for it. Since the test has been available to me in my office, the frequency with which I request it has multiplied many times, the service to the patients is greater, and, in cases of pathological pregnancy, medical care is of a higher standard. The frog test is also of value as a routine preoperative test. The most astute diagnostician will sometimes discover an early pregnancy at the time of laparotomy; routine preoperative frog tests would help eliminate this error.

CONCLUSIONS

The frog test, with either serum or urine, for pregnancy is recommended as a routine office procedure. The use of serum is much simplier and apparently equally or more accurate. Seasonal variations in frog reactivity has proved to be no handicap if strict adherence to the routine procedures outlined is maintained. On the basis of the results of the 450 tests reported, I believe the accuracy of the frog test, in normal pregnancies, is at least 98%. In instances of pathological pregnancies, the result of the frog test is helpful in determining prognosis and instituting treatment.

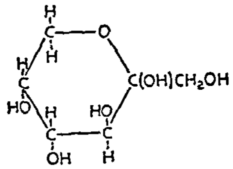
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. STORMONT, M.D., *Secretary.*

Fructose.—Levugen (Mead Johnson).—$C_6H_{12}O_6$.—M.W. 180.16.—Levulose.—Fructose is prepared by the inversion of aqueous solution of sucrose and subsequent separation of fructose from glucose. The structural formula of fructose may be represented as follows:



Actions and Uses.—Fructose (levulose) like dextrose, administered intravenously in solution, is useful for parenteral carbohydrate alimentation when either fluid or calories are required to replace or supplement the oral consumption of water or food. Fructose is more rapidly metabolized and more rapidly converted to liver glycogen than is dextrose. When infused at comparable rates, it results in lower levels of blood sugar and less urinary spillage. Fructose is metabolized or converted to glycogen in the absence of insulin, but the clinical application of this has not been fully determined.

Fructose can be infused at the same rate as but in twice the concentration of dextrose, with better retention and less disturbance of fluid balance. Thus fructose can be employed safely to supply calories more rapidly than either dextrose or invert sugar (half dextrose and half fructose) and to provide more nearly the carbohydrate requirements of patients who need parenteral alimentation. Although fructose is not toxic, excessively rapid intravenous infusion is contraindicated as with other parenteral solutions.

Dosage.—Fructose is administered by intravenous infusion as a 10% solution in water. It can be administered at the same rate as a 5% solution of dextrose. The total daily amount required varies with the patient. For adults the usual initial dose is 1 liter; the average dose, 2 liters; and the maximum dose, 3 liters. For children the total daily amount is determined on the basis of the size and total blood volume of the child. In infants this usually ranges from 0.1 to 1 liter and in children from 0.2 to 2 liters. If administered in quantities in excess of the amounts indicated, any unutilized portion will be excreted in the urine.

Since fructose decomposes in alkaline solution, substances which would raise the pH to values above 7.0 should be added only if the solution is to be administered promptly. Compounds of calcium and barium form insoluble complexes when the pH exceeds 7.0 and are therefore incompatible. Cloudy solutions should not be used.

Tests and Standards.—

Dosage Forms of Fructose

SOLUTIONS. (10%) *Physical Properties:* The solution is clear and colorless. The specific gravity is 1.033-1.039, the refractive index is 1.346-1.348, and the pH is 3.0-3.5.

Identity Tests: To 5 ml. of hot alkaline cupric tartrate T.S. add a few drops of 10% fructose: a red precipitate of cuprous oxide appears *(presence of reducing sugars).*

Prepare a 0.05% solution of resorcinol in hydrochloric acid diluted 1:1. To 5 ml. of the solution add 1 ml. of 10% fructose and heat in a boiling water bath for 2 min.: a cherry-red color appears *(presence of ketohexose)*

Prepare a solution containing 1 gm. of phenylhydrazine hydrochloride and 1.5 gm. of sodium acetate in 10 ml. of water by heating the mixture to about 60°, cooling, and filtering. To 5 ml. of this solution in a test tube add 1.5 ml. of 10% fructose. Place the test tube in a boiling water bath for about 5 min. Crystals begin to appear in 2.0-2.5 min. Cool the reaction mixture, filter it, and wash the precipitate with three 10 ml. portions of water followed by single washings with 5 ml. of alcohol and 5 ml. of ether. Dry the residue at 105° for 30 min.: the yellow osazone formed melts at 205-210° (with decomposition).

The specific rotation, $[\alpha]25,\mathrm{D}$, of 10% fructose is between −90.0 and −94.5°.

Purity Tests: To 10 ml. of 10% fructose add 1 ml. of ammonium oxalate T.S.: the solution remains clear for 1 min. *(absence of calcium).*

To 50 ml. of 10% fructose add 2 ml. of nitric acid and exactly 10 ml. of 0.02 *N* silver nitrate. Heat the mixture on a steam bath to coagulate the silver chloride, cool, and add 5 ml. of nitrobenzene and 2 ml. of ferric ammonium sulfate T.S. Titrate the excess silver nitrate with 0.02 *N* ammonium thiocyanate. Each milliliter of 0.02 *N* silver nitrate consumed is equivalent to 0.0007092 gm. of chloride: the amount of chloride does not exceed 0.025%.

Dilute 1 ml. of 10% fructose to 25 ml. with water, add 1 ml. of barium chloride T.S., shake, and allow the mixture to stand for 1 min.: the turbidity does not exceed that of 0.2 ml. of 0.02 *N* sulfuric acid diluted to 25 ml., and treated in the same manner *(presence of not more than 0.2% sulfate).*

Transfer to a test tube 10 ml. of 10% fructose. Add 5 ml. of ether and shake vigorously. Separate the layers, transfer 2 ml. of the ether layer to a test tube, and add 1 ml. of a 1% solution of resorcinol in hydrochloric acid: a slight pink color may form but no cherry-red color appears immediately *(absence of hydroxymethylfurfural).*

Transfer exactly 10 ml. of 10% fructose to a tared crucible and remove the water by evaporation on a steam bath. Char the residue, cool, add 1 ml. of concentrated sulfuric acid, and continue ignition until no carbon remains: the amount of residue does not exceed 0.5%. Save this residue for the heavy metals test.

To the residue from ashing add a mixture of 30 ml. of diluted hydrochloric acid and 3 ml. of bromine T.S., cover the crucible, and boil gently for 10 min. Filter, and wash the filter and residue with 25 ml. of hot water. Evaporate the filtrate to dryness, dissolve the residue in 15 ml. of water, add 2 ml. of diluted acetic acid, and dilute to 25 ml. with water. Prepare a standard with 0.5 ml. of U. S. P. standard lead solution, and treat it with the same quantities of the same reagents and in the same manner. Run a *U. S. P. heavy metals test:* the amount of heavy metals does not exceed 5 ppm.

Assay: (Fructose) Prepare a 0.4% solution of fructose and using 20 ml. of this solution assay for fructose as directed in *Official Methods of Analysis of the Association of Official Agricultural Chemists,* ed. 7, A.O.A.C., Washington, 1950, p. 508 and 512-513, par. 29.40, 29.41, 29.54, and 29.55. The amount of fructose is not less than 95.0 nor more than *105.0%* of the labeled amount.

Mead Johnson & Company, Evansville, Ind.

Solution Levugen 10%: 1 liter bottles. A solution containing 0.1 gm. of fructose in each cubic centimeter.

APPROVED INTERNSHIPS AND RESIDENCIES IN THE UNITED STATES

ANNUAL REPORT OF INTERNSHIPS AND RESIDENCIES BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Edward H. Leveroos, M.D., and Warren R. Von Ehren

Annual Report

The Council on Medical Education and Hospitals presents in this 27th Annual Report, statistical data and other information on Council-approved internship and residency programs. In addition to the customary tables on the number of internships and residencies, there is a breakdown of internship stipends for nonfederal hospitals, a report on the study made by the Advisory Committee on Internships, and a brief discussion of the National Intern Matching Plan. As in previous years, lists of approved internships and residency programs follow the report. These lists are published in reprint form as the Directory of Approved Internships and Residencies.

The report is based on information submitted for the fiscal or calendar year by hospitals conducting approved training programs. The statistical tables include information on the number of internships and residencies as of Sept. 1, 1952. The data differ therefore, from those contained in the lists of approved services, since these relate to appointments for the year beginning July 1, 1954.

Approved programs are listed as follows: a section on internships based on the state and city in which the hospital is located as well as one based on the type of internship being offered, a section on residency programs by specialties, and a section recapitulating the programs for which each hospital is approved.

The geographical list of approved internships includes data on the type of hospital, bed capacity, annual admissions, autopsy percentage, and stipend, as well as information on the type and number of internships. For those hospitals participating in the official plan for intern appointments, as sponsored by the National Intern Matching Plan, Inc., a code designation is given to each program offered. The list of approved residencies as classified by specialties includes statistical data for that particular service in addition to the name of the chief of service, number of years for which the program is approved, and other pertinent information.

The publishing of this report and the lists of approved services is made possible through the helpful cooperation of the medical staffs and administrators of hospitals in which approved training programs are being conducted. The Council takes this opportunity to express its appreciation for the excellent support it has received from them, as well as for the valuable contribution of the administrative officers of medical schools and the federal services this year, as in the past. To the following organizations with which the Council collaborates in the approval and listing of residency programs, the Council wishes to make grateful acknowledgment:

Advisory Board for Medical Specialties
American Board of Anesthesiology
American Board of Dermatology and Syphilology
American Board of Internal Medicine
  Subspecialty Board on Allergy
  Subspecialty Board on Cardio-Vascular Diseases
  Subspecialty Board on Gastroenterology
  Subspecialty Board on Pulmonary Diseases
American Board of Neurological Surgery
American Board of Obstetrics-Gynecology
American Board of Orthopedic Surgery
American Board of Otolaryngology
American Board of Pathology
American Board of Pediatrics
American Board of Physical Medicine and Rehabilitation
American Board of Plastic Surgery
American Board of Preventive Medicine
American Board of Proctology
American Board of Psychiatry and Neurology
American Board of Radiology
American Board of Surgery
American Board of Urology
Board of Thoracic Surgery
American College of Physicians
American College of Surgeons

The Annual Report is published for the information of members of the medical profession, educators, hospital administrators, and others interested in graduate medical education. The Directory of Approved Internships and Residencies as reprinted from the following lists of approved services has been designated as an official directory by a number of federal and state governmental agencies. Inquiries regarding the report and the directory should be made to the Council on Medical Education and Hospitals.

Internships

For the first time in several years, the number of internships in approved hospitals has decreased from that of the year previous. Last year, 865 hospitals offered 11,467 internship appointments. This year, 856 hospitals indicated that they had 11,006 internship positions available for the year beginning July 1, 1953. While the decrease, 3.4%, was not great, it may indicate a leveling off of the inflationary trend which has occurred over the past 10 years. It can reasonably be anticipated however, that a further voluntary decrease of any sizeable proportion is unlikely in view of the continuing demand for hospital services and the utilization of intern staffs to supply part of those services. In considering the over-all problem of the shortage of interns, it is significant to note that, while the number of hospitals offering approved intern training has increased 12% during the past 10 years, from 760 hospitals to 856, the number of internships in those hospitals has risen 32%, from 8,180 to 11,006 (table 1).

INTERNSHIPS BY TYPE OF SERVICE

A breakdown of the number of internships filled and vacant by type of service is shown in table 2. The number of approved hospitals offering internships in each category is also included. There were a total of 10,548 internships of all types reported by approved hospitals as of Sept. 1, 1952. Of these, 9,497, or 90%, were rotating. This represents an increase in this type of internship of approximately 6% over the previous year.

TABLE 1.—*Approved Hospitals and Internships, 1943-1953*

Year*	Number of Hospitals	Number of Internships
1943	760	8,180
1944†	766	5,602
1945	785	8,429
1946	798	8,584
1947	764	8,539
1948	807	9,118
1949	807	9,124
1950	790	9,398
1951	828	10,044
1952	865	11,467
1953	856	11,006

---

* Year of publication.
† Quota year.
(U. S. Army, U. S. Navy Hospitals and those outside the United States not included in 1943 to 1947 figures.)

Approximately 9%, or 921 internships offered last year, were straight services, while 1%, or 130, were of the mixed type. A total of 7,645 interns were reported on duty as of Sept. 1, 1952. This figure includes second year interns and graduates of foreign medical schools as well as first year interns from schools in the United States. Considering the number of these latter graduates, it can be estimated that from 1,300 to 1,400 internships in the United States are being filled by graduates of schools outside the U. S.

The percentage of internships filled varied somewhat according to type, with 80% of straight internships, 78% of the mixed type, and 72% of rotating internship positions occupied. The comparatively low percentage for the rotating type could be anticipated in view of the large number of these internships available.

The percentage of internships filled has remained the same for the past two years, 72%. During this period, hospitals have reported internship vacancies numbering about 3,000; 3,111 for 1951 and 2,903 for 1952. In considering the problem of the shortage of interns, this over-all figure can be considered more accurate than that obtained by comparing the total number of internships available with the annual number of medical school graduates in this country.

TABLE 2.—*Number of Internships by Type of Service, 1952-1953*

INTERNSHIPS BY TYPE OF HOSPITAL CONTROL

Statistical data relative to the number of internships considered from the standpoint of hospital control are given in table 3. Of the total number of interns on duty as of Sept. 1, 1952, the federal hospitals accounted for approximately 6%, other governmental hospitals (nonfederal) 36%, and the nongovernmental group, 58%. Approximately 68% of the internships offered in federal hospitals were filled. The relatively low percentage for these hospitals was due in large part to the fact that internships in Veterans Administration hospitals were less than one-third filled; other federal hospitals showed internship occupancy rates from 74% in the U. S. Naval hospitals to 99% for the United States Public Health Service hospitals, all being above the occupancy rate for the United States as a whole. Internships in governmental hospitals of the nonfederal group were also comparatively well filled, ranging from 79% in hospitals under state control to 92% in city-county hospitals. As was the case last year, one of the lowest occupancy rates was for the church-controlled group, with 64% of these internships filled.

TABLE 3.—*Number of Internships by Type of Hospital Control, 1952-1953*

Control	Number of Approved Hospitals	Number of Internships		
		Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952
Federal				
U. S. Army	9	174	17	91
U. S. Navy	13	125	43	74
U. S. Public Health Service	5	71	1	99
Veterans Administration	13	67	147	31
Other Federal	2	23	7	77
Totals	42	460	215	68
Governmental (Non-Federal)				
State	24	586	158	79
County	34	734	134	85
City	56	1,199	295	80
City-County	14	235	20	92
Totals	128	2,754	607	82
Non-Governmental				
Church-Related	269	1,555	871	64
Non Profit Assn.-Corp.	361	2,476	1,071	70
Other Non Profit	40	350	124	74
Other Non-Governmental	13	50	15	72
Totals	683	4,431	2,081	68
Grand Totals	853	7,645	2,903	72

It should be noted also that the average number of internships available in these hospitals is 9, compared to 16 for the federal hospitals and 19 for the other government institutions. The failure of the church-controlled hospitals to fill at least two-thirds of their requested number of internships might be expected to have an even more serious effect on their intern programs than would be the case if their intern staffs were larger.

INTERNSHIPS BY MEDICAL SCHOOL AFFILIATION AND HOSPITAL BED CAPACITY

For purposes of this report and in the list of approved internships, hospitals have been classified as "major teaching," "minor teaching," and "nonaffiliated," on the basis of the extent to which these hospitals participate in a medical school's undergraduate teaching program. Thus, a "major teaching" hospital is one which has been designated by a medical school as being a major unit in its undergraduate clinical clerkship program, a "minor teaching" hospital is one utilized to a limited extent for undergraduate instruction, and a "nonaffiliated" hospital is one which does not participate in such a program.

Of the total number of approved hospitals last year, 146, or 17%, were designated as major units in a medical school program. They offered 3,712 internships, or 35% of all positions available (table 4). There were 88 hospitals, or 10%, classified as minor teaching units in which 1,105 internships were offered, representing about 10% of the total. Hospitals without medical school affiliation numbered 619, or 73% of the total number of hospitals approved. In this group, there were 5,731 internships as of Sept. 1, 1952, or about 55% of the total number.

The highest percentage of internships filled, 85%, was in the group of major teaching hospitals of 325 to 399 bed size. Nonaffiliated hospitals of 176 beds or less had the lowest percentage of internships filled, 58%. Aside from this group, however, there were no great differences in the percentages of positions filled in comparing the nonaffiliated hospitals with those classified as "minor teaching." In one group, those of 325 to 399 bed capacity, nonaffiliated hospitals filled a higher percentage, 67%, than did those of the same range in the minor teaching group, which had 63% of their internship positions occupied. Considering the groups as a whole, the major teaching hospitals were the most successful in obtaining interns, with 81% of all internships filled. Minor teaching hospitals had 70% of their positions occupied, and the nonaffiliated group, 67%.

In general, hospitals of larger bed capacities, irrespective of medical school affiliation, obtained higher proportions of interns sought than did the smaller hospitals. Combining the data for all three groups, major, minor, and nonaffiliated hospitals, the percentages of internships filled in hospitals of bed capacities of 176 or under, 250 to 324 beds, and over 400 beds were respectively 60, 70, and 80%.

TABLE 4.—*Number of Internships by Medical School Affiliation and Bed Capacity, 1952-1953*

Classification	Number of Approved Hospitals	Number of Internships: Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952

INTERNSHIPS BY CENSUS REGION AND STATE

The number of internships filled and vacant by states, with a recapitulation by census region, is given in table 5. The East North Central states had the largest percentage of internships filled, 76%, slightly above the national average. All other regional areas showed percentages approximating that for the United States as a whole. The relatively low percentage of internships filled in Mon-

tana, 36%, and the high percentage of those filled in New Hampshire, 100%, are understandable on the basis of the number of internships involved.

Almost half of all hospitals approved for intern training are located in the eight states making up the Middle Atlantic and East North Central regions. They offer a total of 5,009 internships, or about 50% of the total number. About three-fourths of the hospitals offering approved internships lie east of the Mississippi River. They offer a total of 7,438 internships, or 70% of those available. New York with 109, Pennsylvania with 76, and Illinois with 62 hospitals approved for intern training account for 30% of the total number. There are now approved hospitals in all but four states: Idaho, New Mexico, Nevada, and Wyoming.

INTERNSHIP STIPENDS

Table 6 gives an analysis of internship stipends paid in nonfederal hospitals. The figures represent salaries paid to interns in the majority of cases in addition to maintenance. Federal hospitals have been excluded from this table. Stipends paid to interns in these hospitals are established in accordance with government pay tables, with the exception of those paid by the Veterans Administration. Intern stipends in these hospitals are determined locally on the basis of the pay scale prevailing in the community. In hospitals affiliated with medical schools, 36% of intern stipends were at the rate of $75 per month or less, with four hospitals offering no cash stipend; 39% of the hospitals of this classification offered stipends between $76 and $150, and 25% paid salaries of over $150 monthly. For the nonaffiliated group, 7% offered $75 or less per month, 47% paid from $76 to $150, and in 46% the intern monthly stipend was over $150.

Compared with a year ago, internship stipends can be shown to have increased significantly. Comparable figures for the reporting year 1951 gave the following percentages: medical school affiliated hospitals, 56% of stipends in the range $75 per month or less, 35% in the $76-150 range, and 9% reporting stipends of more than $150 per month. In nonaffiliated hospitals percentages for the same salary ranges were 26%, 58%, and 16%. The number of approved hospitals in both groups, affiliated and nonaffiliated, which paid stipends of $200 per month or over rose from 20 as of Sept. 1, 1951, to 104 as of Sept. 1, 1952. The majority of hospitals paying stipends in this range are those of less than 325 bed capacity in the nonaffiliated group.

ADVISORY COMMITTEE ON INTERNSHIPS

Late in 1952, the Advisory Committee on Internships completed an intensive study of the internship and its place in present-day medical education, a study which had been in progress for more than 15 months. The committee included representatives from the medical profession, medical education, the major specialties, and hospital administration, as follows:

S. Howard Armstrong, Chicago.
Granville Bennett, Chicago.
Ulrich Bryner, Salt Lake City.
John Leonard, Hartford, Conn.

The committee made a report of its findings which was published in The Journal[1] early this year. The report summarized the committee's views on the form and content of the internship and the manner in which it should be conducted. Since its publication, the report has received recognition as an outstanding contribution to this field of medical education and one which will serve to redefine and clarify the principles of intern education for some time to come.

In addition to having drawn up this report, the committee made a thorough study of the Essentials of an Approved Internship and recommended revisions which were officially adopted. The more important changes were those relating to the organization and conduct of an intern educational program, along with those concerning the responsibilities of the medical staff and interns. Changes were also made in the quantitative requirements relating to bed capacity, annual admissions, and autopsy rate. A provision that a hospital which failed for two successive years to appoint at least two-thirds of its requested number of interns be reevaluated for continued approval, was subsequently invalidated. The provisions of these revised Essentials of an Approved Internship are now the basis on which a hospital's teaching potential is evaluated in considering it for admission to, or continuance on the approved list.

---

[1] J. A. M. A. **151**: 499-510 (Feb. 7) 1953.

NATIONAL INTERN MATCHING PLAN

The Matching Plan, first introduced in 1950, will again be the official method for the appointment of interns for the coming year. The plan is sponsored by the following organizations: the American Medical Association, the American Hospital Association, the Association of American Medical Colleges, the Catholic Hospital Association, and the Protestant Hospital Association, with liaison representatives to the operating committee from the medical departments of all federal services conducting intern programs. Two student representatives, one from the Student American Medical Association and one representative at large, are also members of the committee.

This year, for the first time, hospitals participating in the Matching Plan have been so designated in the Directory of Approved Internships and Residencies, with code identification of each program in addition to the usual statistical data about the hospital and information on the number and types of internships offered. This section of the directory will be duplicated for the use of students seeking appointments through the plan for the intern year 1954-1955.

The Matching Plan does not purport to distribute interns. A hospital participating in the plan may or may not obtain its requested number of interns, depending upon the number of applicants who signify their desire to accept appointment at that hospital and who are not matched with another hospital higher in their preference rating. The primary purpose of the plan is to give effect to the student's expressed choice of the hospital at which he desires to intern and the hospital's preference of persons applying to it. The plan in no way interferes with the student's free selection of the hospital of his choice. It does have the effect of relieving undue pressure on the student in making that choice. Neither does the plan interfere with proper negotiations between hospital and applicant. It assures the hospital of the appointment of those interns who have applied to it and who have given the hospital high enough preference in their confidential list.

The Matching Plan completed its second successful year of operation last year. A total of 843 hospitals, offering 10,971 internship appointments, participated. There were 6,033 students who signed agreements to apply for appointment through the plan. Of these, 4,873 (80%) were matched with hospitals of their first choice. An additional 580 students (10%) were appointed to hospitals which the applicant had rated second in his confidential list; 291 (5%) received appointments to hospitals they had rated third choice or lower. The remaining 289 students (5%) were not matched with any hospital on their list. The majority of this group had applied to a small number of hospitals, all of which had filled their internships with applicants rated higher by the hospital or the hospitals listed had indicated they would not accept the applicant concerned.

Agreements for participation in the plan for the coming intern year have been forwarded to all approved hospitals, with 835 hospitals indicating that they will participate. Student agreements have also been distributed and are now being returned. It is anticipated that an even higher proportion of students will make their appointments through the plan this year than did last year, when over 90% of the senior class were participants.[2]

Residencies

Residency programs in 27 specialties and subspecialties and in general practice are currently approved by the Council. In 17 specialties in which approved examining boards have been established, the Council collaborates with the board concerned in granting recognition to a hospital for residency training. In three specialties, ophthalmology, physical medicine, and thoracic surgery, approval is given to a program without specifying the number of years for which the hospital is accredited. Credit for training in these specialties is granted by the board on an individual basis. In all other specialties and subspecialties, the number of years of approval has been designated.

Residency programs in internal medicine are approved through the Residency Review Committee for Internal Medicine, representing the Council, the American Board of Internal Medicine, and the American College of Surgeons. Residencies in the medical subspecialties of allergy, cardiovascular diseases, gastroenterology, and pulmonary diseases are approved in collaboration with the respective subspecialty board of the American Board of Internal Medicine. In surgery, residencies are approved in behalf of the Council, the American Board of Surgery, and the American College of Surgeons through the Conference Committee on Graduate Training in Surgery. Through this committee, uniform standards for training in general surgery, a single list of approved programs, and a uniform evaluation procedure have been established.

---

[2] Further details on the operation of the plan can be obtained from the office of the Director, National Intern Matching Plan, Inc., 185 N. Wabash Ave., Chicago, Ill.

In 1950, a special category of residency programs in surgery was developed. These programs are approved by the Council, acting independently, as offering satisfactory training in general surgery in preparation for a surgical specialty. Most of the boards in the surgical specialties now either require or recommend a minimum of one year of such training before beginning training in the specialty itself. Programs of this type have been designated under the category Surgery B in these tables. Surgical residencies leading to certification by the American Board of Surgery are designated as Surgery A programs. Hospitals developing residency programs in general surgery and applicants applying for appointments in surgery should take note of the differentiation between these two types of surgical residencies.

NUMBER OF RESIDENCIES BY SPECIALTIES

This year, there were a total of 4,634 residency programs conducted in 1,131 hospitals approved by the Council. A total of 22,292 residency positions were available in these hospitals, 10,285 being first year appointments. Table 8 includes data on these programs, including the number approved, the number of positions filled and vacant as of Sept. 1, 1952, and the percentages filled, by specialty.

Considering first year appointments only, the largest number offered were in psychiatry, with a total of 1,833 positions; 1,780 first year residencies were available in internal medicine, and 1,500 in general surgery (Type A). Specialties in which the largest percentage of first year positions were filled included gynecology only, 91%, thoracic surgery 89%, obstetrics-gynecology, 84%, psychiatry 84%, surgery (Type A) 84%, and pediatrics, 82%. Considering the total number of residency positions filled, thoracic surgery with 90%, obstetrics-gynecology, 88%, surgery (Type A) 86%, ophthalmology 84%, pediatrics, 84%, and plastic surgery, 82%, showed the largest percentages.

The programs with the lowest percentage of total residencies filled included proctology, 40%, allergy, 46%, physical medicine, 49%, general practice, 51%, surgery (Type B) 56%, and pathology 58%. In these fields, the percentage of positions filled was appreciably below the average for all specialties.

There were 16,867 residency positions filled last year, representing 76% of the total number offered. This compares with 15,851 residencies filled a year ago, representing 77% of those available. It can be anticipated that this figure will remain relatively constant for the next few years unless there is a marked increase in the number of applicants available following discharge from the military services.

As commented on in the Annual Report last year, the percentage of residencies filled in hospitals throughout the United States now closely approximate that for internship positions, 76% as compared to 72%. It is apparent that the staffing of hospitals with interns and residents should be considered as two facets of the same basic problem. An evaluation of the intern shortage except in terms of the total problem can supply at best only a partial answer.

RESIDENCIES BY TYPE OF HOSPITAL CONTROL

Table 9 represents an analysis of residency positions by type of hospital control. Federal hospitals, 109 in number, with 647 separate programs offer 1,393 first year positions, or 14% of the total, and 3,708 residencies for all levels, representing 16% of these appointments. Within the federal services, Veterans Administration hospitals accounted for 80% of the first year residencies and for 75% of the total number of appointments to federal hospitals.

TABLE 8.—*Number of Residencies by Specialty, 1952-1953*

Specialty	Number of Approved Programs	Number of Residencies: First Year Appointments: Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952	Total Appointments (All Years): Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952

Totals	4,634	7,777	2,508	76	16,867	5,425	76

Surgery A—Programs leading to certification by the American Board of Surgery.

Surgery B—Programs approved as offering training in general surgery in preparation for a residency in a surgical specialty.

Other governmental hospitals, excluding federal, offered 4,025 first year appointments, or 39% of these residencies, and 7,553, or 36% of all residency appointments. There were 2,755 residency programs conducted in 727 nongovernmental hospitals throughout the country. These included nonprofit association, church-related, and other community-type institutions. They offered 4,867 first year appointments, or 47% of these residencies, and 11,031 appointments at all levels, representing 48% of the total number of positions available. Federal hospitals were the only group to show a lower percentage of first year appointments filled as compared to that for all levels, 69% for the former and 75% for the latter.

The residency occupancy rate for all types of hospitals was 76% for both first year appointments and for positions at all levels. There were 7,777 first year residents reported on duty last year, with a total of 16,867 residents in all categories. Comparable figures for the year previous showed 6,376 first year residents and 15,851 total number of residents.

NUMBER OF RESIDENCIES BY HOSPITAL BED CAPACITY

A breakdown of the number of first year and total appointments filled and vacant for hospitals of varying bed capacities is given in table 10. Over 62% of first year residencies, 6,377 in number, and 61% of all residencies, a total of 13,654 positions, were offered in hospitals of 400 beds or larger. Hospitals of bed capacities from 250 to 399 beds accounted for 2,221 first year appointments, or 22% of this group and 4,676, or 20% of all residency appointments, while hospitals of bed capacities below 250 accounted for the remainder, 16% of first year and 15% of total appointments available (4% of the total number of appointments were in hospitals of unspecified size).

TABLE 9.—*Number of Residencies by Type of Hospital Control, 1952-1953*

Control	Number of Approved Hospitals	Number of Approved Programs	Number of Residencies: First Year Appointments: Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952	Total Appointments (All Years): Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952
Federal								
U. S. Army	16	84	117	41	74	383	75	84
U. S. Navy	7	85	58	5	92	207	72	74
U. S. Public Health Service	8	30	33	4	89	113	12	90
Veterans Administration	72	426	732	366	67	2,021	742	73
Other Federal	6	22	23	14	62	65	6	92
Totals	109	647	963	430	69	2,789	919	75
Governmental (Non-Federal)								
State	143	468	1,969	319	86	2,903	728	80
County	63	243	386	135	74	939	281	77
City	73	437	806	259	76	1,831	549	77
City-County	16	84	122	29	81	254	68	79
Totals	295	1,232	3,283	742	82	5,927	1,626	79
Non-Governmental (all types)	727	2,755	3,531	1,336	73	8,151	2,880	74
Grand Totals	1,131	4,634	7,777	2,508	76	16,867	5,425	76

There appears to be a direct correlation between the size of the hospital and the percentage of residencies filled, particularly for first year appointments, hospitals of bed capacities under 176 having the lowest percentage filled, 66%, and hospitals over 400 beds and over the highest, 80%. Again, for all residencies, hospitals of 176 beds or less filled 69% of their positions while those of 400 beds or over had an occupancy rate of 76%.

RÉSUMÉ

An analysis of internships and residencies available in hospitals approved by the Council has been presented in tabular form together with explanatory comment in this report. There are now 182 hospitals approved by the Council for intern training only, 457 approved for residency training only, and 674 approved for both types of graduate education. A total of 32,840 house staff positions are offered in these hospitals, including 10,548 internship and 22,292 residency appointments.

Last year, 24,512 of these positions were filled, with 7,645 interns and 16,867 residents on duty. It can be estimated on this basis, then, that approximately 15% of the physician population in this country are currently engaged full time in hospital work as house staff members. While the primary objective of these internship and residency programs is educational, their importance from the standpoint of hospital service is evident.

Last year, 28% of all internships and 24% of all residency positions were vacant. While the percentage of vacancies has grown steadily over the past decade, the number of interns and residents serving in approved hospitals has more than doubled. The problem of intern and resident shortages then, is a relative one, depending on whether the demand for interns and residents or the current supply is considered the frame of reference.

TABLE 10.—*Number of Residencies by Bed Capacity, 1952-1953*

Classification	Number of Approved Hospitals	Number of Residencies: First Year Appointments: Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952	Total Appointments (All Years): Filled Sept. 1, 1952	Vacant Sept. 1, 1952	Percentage Filled Sept. 1, 1952
Under 176 beds	246	438	231	66	940	425	69
176-249	227	677	322	68	1,433	610	70
250-324	189	779	379	67	1,600	763	68
325-399	104	805	258	76	1,710	603	74
400-over	360	5,067	1,310	80	10,663	2,991	78
Not specified	5	11	8	58	521	33	94
Grand Totals	1,131	7,777	2,508	76	16,867	5,425	76

Thus, in 1940, while there were few, if any, internship or residency positions unfilled, there were less than 12,000 interns and residents on duty. Conversely, today approximately 25% of all house staff positions are vacant. The number of interns and residents on duty, however, has risen to over 24,000. These facts are significant in any appraisal of the current situation relative to house staff shortages.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association

535 North Dearborn Street, Chicago 10

Revised to September 1, 1953

HOSPITALS, 856, INTERNSHIPS, 11,006

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered in position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three types of internships are approved by the Council—rotating, mixed and straight:

1. A rotating internship is defined as one which provides supervised experience in internal medicine, surgery, pediatrics, obstetrics and their related subspecialties, together with experience in laboratory and radiologic diagnosis.
2. A mixed internship is defined as one which provides supervised experience in two or more, but not in all, of the clinical divisions named.
3. A straight internship is defined as one which provides supervised experience in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery and pediatrics.

Hospitals approved for internships that are used by medical schools for undergraduate clinical clerkships on inpatient services have been identified in the following lists by the symbols **X** and **x**. Hospitals have been identified with symbol **X** when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with the symbol **x** when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program. Certain internships in hospitals designated as teaching hospitals may not provide for assignments to teaching services. Other internships may provide for only a portion of the internship period being spent on teaching services. Prospective interns desiring specific information concerning internship assignments to teaching services in a hospital are advised to communicate with the dean of the medical school with which the hospital is affiliated. Medical school affiliations are indicated by footnotes 10 to 86 placed immediately after the symbol X or x. The list of medical schools appears on page 303. The plus (+) sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables. When applying for internships in Air Force, Army, Navy or Public Health Service hospitals, applications should be directed to the medical departments of the Air Force, Army, Navy or the United States Public Health Service and not to the individual hospitals. Although applications are made to the service rather than to the individual hospitals, all of the services ask students to list three hospitals in order of preference. Every possible effort is made to place successful candidates in accordance with their desires. Because of the needs of the service it should be understood that students may, in some instances, be assigned to other hospitals than those for which they have indicated a preference.

Hospitals listed below (pages 282 to 302) make first year internship appointments through the National Intern Matching Program, Inc. (see also page 302). The number and type of internships as listed represent appointments for the intern year 1954-1955.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

The following list of hospitals which conform to the standards of the Canadian Medical Association is published for the information of graduates interested in an internship appointment in a Canadian hospital. Hospitals that are unqualifiedly approved as conforming to the standards of the Canadian Medical Association may be considered as offering internships equivalent in educational value to those in hospitals approved for intern training by the Council.

This list, revised to Sept. 1, 1953, has been furnished by the Canadian Medical Association.

Name of Hospital	Location	Name of Hospital	Location	Name of Hospital	Location
St. John's General Hospital	St. John's, Nfld.	Sherbrooke Hospital	Sherbrooke, Que.	Grace Hospital	Windsor, Ont.
Camp Hill Hospital	Halifax, N. S.	*Hospital General de Verdun*	Verdun, Que.	Hotel Dieu of St. Joseph	Windsor, Ont.
Halifax Infirmary	Halifax, N. S.	Brantford General Hospital	Brantford, Ont.	Metropolitan Hospital	Windsor, Ont.
Victoria General Hospital	Halifax, N. S.	Hamilton General Hospital	Hamilton, Ont.	St. Boniface Gen. Hosp.	St. Boniface, Man.

ABBREVIATIONS AND NOTES

1. Appointments available to women applicants
2. Appointments restricted to women applicants
3. Appointments available to graduates of foreign medical schools. Details regarding requirements for appointment can be secured from the hospitals concerned.
4. Dental internships available
5. Available to citizens of the United States only
6. General Practice internships

* Male patients only.

+ The plus sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships.

CyCo	City and County	Op	Optional
Corp	Corporation unrestricted as to profit	Req	Required
NPAssn	Nonprofit association		
Part	Partnership		

Medical School Affiliations

Footnotes 10 to 86 refer to medical schools affiliated with hospitals for undergraduate clinical clerkships.

Hospitals have been identified with symbol X when a medical school has indicated that the hospital is a major unit in the school's teaching program.

Hospitals have been identified with symbol x when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program.

APPROVED RESIDENCIES AND FELLOWSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1953

Hospitals, 1,159; Assistant Residencies, Residencies and Fellowships, 22,763

The following services are approved by the Council on Medical Education and Hospitals as meeting the requirements of the Essentials of Approved Residencies and Fellowships. In those specialties in which certifying boards have been established approval is extended in concurrence with the Board concerned. The number of years of training for which approval has been granted is indicated in the column, "Length of Approved Program (years)." Residencies in which this designation does not appear have been approved without specifying the number of years for which they are accredited. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables.

INDEX TO LIST

15. ORTHOPEDIC SURGERY

Type of training acceptable to Board: A—Adult orthopedics; C—Children's orthopedics; F—Fractures. The following services have been approved by the Council and the American Board of Orthopedic Surgery as offering *acceptable training in adult orthopedics, children's orthopedics and fractures.* Training in the basic sciences is given either as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated by a program number, a list of which is found on page 338.

Residents *completing their training in these hospitals* are eligible for full certification by the American Board of Orthopedic Surgery, including children's orthopedic surgery.

Hospitals, 199; Assistant Residencies and Residencies, 727

15. ORTHOPEDIC SURGERY—Continued

The following services have been approved by the Council and the American Board of Orthopedic Surgery as offering acceptable training in adult orthopedics and fractures. Training in the basic sciences is given as an integral part of these services or as a separate course. Services collaborating in an integrated plan of training are designated by a program number, a list of which is found on page 338.

Residents completing their training in these hospitals are eligible for limited certification by the American Board of Orthopedic Surgery, not to include children's orthopedic surgery.

The following services are approved by the Council and the American Board of Orthopedic Surgery as offering acceptable training in one or more but not all categories of orthopedic surgery. Hospitals included in this list are urged to develop a full three year program, either independently or in collaboration with other institutions in order to assure applicants for appointment of an opportunity for completing their training with progressive graded responsibility.

Hospitals, 30; Assistant Residencies and Residencies, 56

17. PATHOLOGY

The following services have been approved by the Council and the American Board of Pathology. Services which have been evaluated on the basis of training in the two categories, pathologic anatomy and clinical pathology, are designated as follows: a—pathologic anatomy only; c—clinical pathology only; p—pathologic anatomy and clinical pathology. Training in hospitals which are not so designated in this list will be evaluated by the Board on an individual basis at the time of application for certification.

21. PREVENTIVE MEDICINE AND PUBLIC HEALTH

The following programs have been approved for two years of training by the Council and the American Board of Preventive Medicine.

Department of Health	Location	Director	Local Areas	Population	Stipend (Month)
State of California	San Francisco	W. L. Halverson	Alameda County (a)	214,600*	$400 max.
			San Joaquin Local Health Dist.	224,500*	....
State of Delaware	Dover	F. I. Hudson, Ex. Sec.	Kent and Newcastle Counties (b)	153,009*	$100-500 (c)
State of Florida	Jacksonville	W. T. Sowder	Alachua County	61,950*	$475-500
			Dade-Miami	612,900*	....
			Hillsborough-Tampa	277,730*	....
			Pinellas-St. Petersburg	178,070*	....
State of Illinois	Springfield	R. R. Cross	Cook County (d),(e)	743,938	$416-500
			Will County (e)	134,336	....
State of Kansas	Wichita	T. B. Hood	Kansas City-Wyandotte	172,762	(f)
			Topeka-Shawnee	116,774	....
			Wichita-Sedgwick	272,000	....
State of Maryland	Baltimore	R. H. Riley	Anne Arundel County	128,401*	(g)
			Baltimore County	290,024*	
			Eastern Health District of Baltimore City	108,299*	
			Montgomery County	182,511*	
			Washington County	81,147*	
State of Massachusetts	Boston	V. A. Getting	(h)	(h)	$450 (i)
State of Michigan	Lansing	A. E. Heustis	Barry County	27,000*	$400
			Calhoun County	120,813	....
			Detroit	1,849,568	....
			Wayne County (j)	490,673	....
State of Minnesota	Minneapolis	A. J. Chesley, Secy. and Ex. Off.	Olmstead-Rochester	49,914*	75% of What job will pay (k)
New York City	New York City	J. F. Mahoney	Fort Greene	221,918	$390
			Jamaica West	274,169	....
			Red Hook	172,391	....
			Tremont	304,601	....
State of New York	Albany	H. E. Hilleboe	(l)	(l)	$425
State of North Carolina	Raleigh	J. W. R. Norton	Charlotte-Mecklenburg County	211,754*	$500
			Forsyth-Winston-Salem	152,524*	....
			Halifax	58,981*	....
			Orange-Person-Chatham-Lee	112,955*	....
State of Virginia	Richmond	M. I. Shanholtz	Arlington County	150,000*	$687.50
State of Washington	Seattle	J. A. Kahl	Kitsap-Bremerton	75,724	....
			King-Seattle	732,992	$500
			Clark-Skamania	90,095	$580

---

* Estimated.

(a) Excludes Alameda, Berkeley and Oakland cities with full time health officers, and Albany and Livermore with part-time officers.

(b) Excludes the city of Wilmington.

(c) To those planning to work in state; transportation costs only to others.

(d) Excludes Berwyn, Chicago, Evanston, Oak Park, Stickney Township, and Winnetka (including Glencoe, Kenilworth, Northbrook, and remainder of New Trier Township), all with full time health officers.

(e) Opportunity available to secure master's degree in public health.

(f) Arrangements for remuneration made on an individual basis.

(g) Arrangements for remuneration made upon determination of field of interest and location desired.

(h) Training is given in a combination of one county, one union health and seven municipal health departments, and in the divisions of the State Department of Health.

(i) To those training for service in Massachusetts only.

(j) Excludes Detroit and Dearborn, each with full time health officers.

(k) To those training for service in Minnesota only.

(l) Training is given in any one of ten City Health Departments, 14 County Health Departments, or 15 District Offices within the State.

Numerical and other references will be found on pages 373 and 374.

22. PROCTOLOGY

The following services have been approved by the Council and the American Board of Proctology. Residencies in this specialty have been approved without specifying the number of years for which they are accredited. The Board will give appropriate credit for training in these hospitals on an individual basis.

Hospitals, 12; Assistant Residencies and Residencies, 49

PSYCHIATRY PROGRAM IDENTIFICATION

10. Service in child psychiatry.
11. Six months service at Los Angeles County Hospital, Los Angeles.
12. Nine months service at Mount Zion Hospital, six months at Langley Porter Clinic and service in child psychiatry, San Francisco.
13. Three months of service at Napa State Hospital, San Francisco Hospital, Strickton State Hospital, Sonoma State Home and San Quentin Prison; and six months at Colwell Memorial Hospital.
14. Three months service Fort Miley Veterans Administration Hospital, San Francisco, and Langley Porter Clinic, San Francisco; may include elective services at University of California Hospital, Mount Zion Hospital and Stanford University (Lane) Hospital, San Francisco.
15. Three months service at Pacific Colony Hospital, Spadra and three months service in child psychiatry at Camarillo State Hospital.
16. Affiliate services at Colorado General and Denver General Hospitals.
17. Affiliate service at Veterans Administration Hospital, West Haven, Connecticut State Hospital, Fairfield State Hospital, Norwich State Hospital and service in child psychiatry.
18. Twelve months service at University Services, Grace-New Haven Community Hospital, New Haven, Connecticut.
19. Six months service at Governor Bacon Health Center, Delaware City.
20. Two months service at George Washington University Hospital, Washington, D. C.
21. Affiliate service at University Hospital, Augusta, Georgia.
22. Twelve months service at the Neuropsychiatric Institute of the University of Illinois including service in child psychiatry.
23. Eighteen months affiliate service including service at the Neuropsychiatric Institute of the University of Illinois and three months in child psychiatry.
24. Affiliate service at Neuropsychiatric Institute of the University of Illinois and service in child psychiatry.
25. Three months service at Veterans Administration Hospital, Downey, Illinois and service in child psychiatry.
26. Six months service at Veterans Administration Hospital, Hines, Illinois. May include service in child psychiatry.
27. Six months service in child psychiatry.
28. Integrated program including service at Veterans Administration Hospital, Indianapolis General Hospital and Indiana University Medical Center and Affiliated Hospitals, Indianapolis.
29. Integrated program including service at Veterans Administration Hospital, Menninger Sanitarium and Topeka State Hospital, Topeka, Kansas.
30. Four months service at University of Louisville Services, Louisville, Kentucky and four months service at Cincinnati General Hospital, Cincinnati, Ohio.
31. Three months service at University of Louisville Services, Louisville, Kentucky.
32. Twelve months service at University of Louisville Services. May include four months service at Central State Hospital; four months service at Louisville General Hospital.
33. Four months service at Central State Hospital and service in child psychiatry.
34. Integrated program including service at Tulane University Unit, Charity Hospital, New Orleans, and Veterans Administration Hospitals, New Orleans, and Gulfport, Mississippi.
35. Six months service in child psychiatry and twelve months service at South Louisiana State Hospital.
36. Service in child psychiatry; six months service at Veterans Administration Hospital, Perry Point, Maryland.
37. Three months service in child psychiatry at Johns Hopkins Hospital (Harriet Lane House), Baltimore, Maryland.
38. Twelve months service at Boston State Hospital and service in child psychiatry.
39. Twelve-eighteen months service at Veterans Administration Hospital, Boston (Jamaica Plain), Massachusetts, and six months service in child psychiatry.
40. Integrated program including service at Massachusetts General Hospital and McLean Hospital, Waverly.
41. Twelve months service at University Hospital, Ann Arbor, Mich.
42. University Hospital, Ann Arbor, Michigan.
43. Three months service Coldwater State Home and Training School, Caro State and Ionia State Hospitals and service in child psychiatry.
44. Six months service in child psychiatry at Children's Hospital, Detroit.
45. Six months service at City of Detroit Receiving Hospital, Children's Hospital, Detroit, and Wayne County General Hospital and Infirmary, Eloise, Michigan.
46. University of Minnesota Hospitals, Minneapolis, Minnesota.
47. Three months service at Rochester State Hospital, Rochester, Minn.
48. Affiliate service at Barnes Hospital, St. Louis and three months at St. Louis State Hospital.
49. Six months service at Barnes Hospital, St. Louis, Missouri.
50. Service at St. Louis State Hospital and St. Louis City Hospital.
51. Service at Lutheran Hospital, Omaha.
52. Service at University of Nebraska Hospital.
53. Affiliate service at University of Nebraska Hospital and Creighton Memorial-St. Joseph Hospital, Omaha, Nebraska.
54. Six months service at Newark City Hospital; three months at New Jersey State Hospital and three months in child psychiatry.
55. Three months service at Albany Hospital, Albany, New York.
56. Affiliate services at Edward J. Meyer Memorial Hospital and Buffalo State Hospital.
57. Six months service at King's County Hospital, Brooklyn, New York.
58. Integrated program with service at Bellevue Hospital Center and University Hospital.
59. Six months service at Mount Sinai Hospital, New York City.
60. Service in child psychiatry. May include six months service at Mount Sinai Hospital and three months at Manhattan State Hospital.
61. Twelve months service at New York Hospital and four months at Veterans Administration Hospital, New York City (Bronx), New York.
62. Three months service at Grasslands, Rockland State, Albany Hospitals and Letchworth Village.
63. Six months service at Rochester State Hospital, Rochester, New York.
64. Six months service at Strong Memorial-Rochester Municipal Hospitals, Rochester.
65. Affiliate service at Strong Memorial-Rochester Municipal Hospitals.
66. Three months service at Syracuse Memorial, Binghamton, Syracuse and Willard State Hospitals, service at Craig Colony and service in child psychiatry.
67. Affiliate service at State Hospitals at Raleigh and Butner, North Carolina.
68. Eighteen months service at Duke Hospital, Durham, North Carolina.
69. Three months service at Longview State and Jewish Hospitals, Cincinnati.
70. Integrated program including service at Cleveland Clinic and Windsor Hospital.
71. Integrated program including service at University Hospital and Veterans Administration Hospital, Cleveland, Ohio.
72. Integrated program with service at Institute of the Pennsylvania Hospital and Pennsylvania Hospital Department for Mental and Nervous Diseases.
73. Affiliate services at Temple University Hospital, Institute of Pennsylvania, Hospital of the Woman's Medical College of Pennsylvania.
74. Six months service at Philadelphia General Hospital and service in child psychiatry.
75. Two months affiliate service for institutional care.

76. Integrated program including servic Hos-
pital, Veterans Administration Hosp nis-
tration Hospital, Murfreesboro and ille.
on,

77. Four months affiliate service at S
Texas.

78. Service in child psychiatry at Jefferson Davis Hospital, Houston, Texas.
79. Six months affiliate service at Veterans Administration Hospital, Salt Lake City, Utah and affiliate services at State Hospital, Provo, Utah.
80. Integrated program including service at University of Virginia Hospital, Charlottesville and Veterans Administration Hospital, Roanoke, Va.
81. Affiliate service at Southwestern State Hospital, Marion and Lynchburg State Colony, Lynchburg, Va.
82. Six months service at Medical College of Virginia—Hospital Division, Richmond and service in child psychiatry.
83. Six months service at Veterans Administration Hospital, American Lake, Washington and six months in child psychiatry.

24. PULMONARY DISEASES

The following services have been approved for one year of training by the Council and the Subspecialty Board for Pulmonary Diseases of the American Board of Internal Medicine.

Hospitals, 110; Assistant Residencies and Residencies, 435

GRADUATE TRAINING PROGRAMS

Acceptable by the American Board of Psychiatry and Neurology Until July 1, 1956

The Council on Medical Education and Hospitals has limited its approval of programs for graduate training to those offered in connection with general or special hospitals. The following information is published, however, at the request of the American Board of Psychiatry and Neurology to indicate the availability of a special type of training which is acceptable to the board and carries full credit toward certification by that board. The board has announced, however, that after July 1, 1956, credit for training in child psychiatry will be granted when such training is integrated with and contributory to an approved residency program. Independent approval of child guidance centers by the American Board of Psychiatry and Neurology will be terminated as of that date.

REQUIREMENTS FOR ACCEPTANCE

In order to facilitate the arrangements for training in child psychiatry (which constitutes a major aspect of modern psychiatry), the American Board of Psychiatry and Neurology will accept one year of training in psychiatric clinics for children which may or may not be a part of a hospital approved for residency training, provided such a clinic gives adequate supervision and instruction for full time training during the entire third year of the required three year formal training period. For the purpose of evaluating such clinics, the following conditions and criteria are deemed essential by the American Board of Psychiatry and Neurology:

1. That the clinic have a full time medical director, psychologist, and social worker qualified by training and experience in child psychiatry and allied fields to supervise the training of residents.

2. That the major portion of such training be devoted to therapy adequately supervised by this qualified staff.

3. That the service and teaching activities of the clinic be integrated with those of the community and its social agencies.

4. That clinic work be supplemented by seminars, case conferences, journal clubs or other opportunities for the discussion of the basic principles involved in outpatient work with children and parents, teacher, public health and welfare agency personnel.

5. That such a training clinic be well established in the community with a qualified staff that has operated together long enough as a team to insure stable and sound functioning.

6. That the senior members of the clinic team show evidence of previous experience in the teaching of psychiatry in general, child psychiatry in particular, and their allied fields.

These criteria set forth by the Board pertain more particularly to community sponsored clinics offering full time training in child psychiatry during the third year of formal residency training. If these clinics are affiliated with hospitals already maintaining approved programs, separate approval is not required unless warranted on the basis of their meeting all requirements for straight fellowship training in child psychiatry.

The following clinics are acceptable to the American Board of Psychiatry and Neurology as qualifying under these provisions until July 1, 1956.

Center	Director
Pasadena Child Guidance Clinic 40 E. Dayton Central Park Pasadena 2, Calif.	Dr. M. B. Durfee
Children's Psychiatric Division Langley Porter Clinic San Francisco	Dr. Stanislaus Szurek
Clifford W. Beers Guidance Clinic 432 Temple Street New Haven 11, Conn.	Dr. William B. Curtis
Institute for Juvenile Research 907 S. Wolcott Ave. Chicago	Dr. Julius B. Richmond
Louisville Mental Hygiene Clinic and Child Study School 610 S. Floyd Street Louisville, Ky.	Dr. Spafford Ackerly
The Guidance Center 1737 Prytania Street New Orleans	Dr. Jack E. Chappuis, Acting Director
The Psychiatric Clinic of the Mental Hygiene Society of Maryland Baltimore	Dr. H. Whitman Newell
Douglas A. Thom Clinic for Children, Inc. 315 Dartmouth Street Boston	Dr. Eveoleen N. Rexford
Judge Baker Guidance Center 38 Beacon Street Boston	Dr. George E. Gardner
Children's Center 244 Townsend Street Roxbury, Mass.	Dr. Marian Putnam and Mrs. Beata Rank, Co-directors
Worcester Child Guidance Clinic 2 State Street Worcester 5, Mass.	Dr. Joseph Weinreb
Amherst H. Wilder Clinic 279 Rice Street St. Paul	Dr. Hyman S. Lippman
Jewish Board of Guardians 228 East 19th Street New York 3	Dr. Joachim Flescher
Central Clinic Cincinnati General Hospital Cincinnati	Dr. Maurice Levine
Cleveland Guidance Center 2525 Euclid Avenue Cleveland	Dr. Claire M. Ness
Child Guidance Clinic 1711 Fitzwater Street Philadelphia 46	Dr. Frederick H. Allen
Pittsburgh Child Guidance Clinic 3004 Victoria Street Pittsburgh 13	Dr. Harry M. Little
Children's Service Center of Wyoming Valley 335 South Franklin Street Wilkes-Barre, Pa.	Dr. J. Franklin Robinson
The Children's Service Center of Charlottesville and Albemarle County, Inc. 116 14th Street, N.W. Charlottesville, Va.	Dr. Frank J. Curran

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES ✓

ADVISORY BOARD FOR MEDICAL SPECIALTIES

B. R. KIRKLIN, Secretary-Treasurer
Rochester, Minn.

The Advisory Board for Medical Specialties was organized in 1933-1934 to coordinate graduate medical education and certification of medical specialists in the United States and Canada. A few specialty boards had been functioning actively and successfully for a number of years prior to the organization of the Advisory Board for Medical Specialties. Their purposes were, primarily, to establish minimum standards of graduate education and training requirements for physicians representing themselves to the public as being specialists, with certification by the boards of candidates after they had been able successfully to pass the boards' examinations. Secondarily, these boards hoped to improve the general standards of graduate medical education and facilities for special training.

It was soon recognized that some formal and official plan of organization must be established. It was clearly essential that an examining board must have the official sanction of the national societies in its given specialty as well as that of its section of the American Medical Association, but there was, at that time, nothing to prevent unofficial groups from organizing examining boards and using the title American board. In order to avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups into a concise and homogeneous plan for betterment, it was deemed advisable to create an advisory board that should give consideration to those problems common to all and that should be representative of all organizations concerned.

The Advisory Board is composed of two representatives from each of the approved examining boards in the medical specialties and such other national organizations as are interested in the education, examination, and certification of medical specialists. These representatives are duly elected to this body.

The number of organizations comprising the Advisory Board for Medical Specialties remains the same; namely, 18 Specialty Boards and 4 other organizations interested in graduate medical education. The total voting membership is still 44. The organizations and their representatives are as follows:

Association of American Medical Colleges
WILLIAM S. MIDDLETON — STANLEY E. DORST *

The American Hospital Association
FRANK R. BRADLEY — ROBIN C. BUERKI *

The Federation of State Medical Boards of the U. S. A.
CREIGHTON BARKER — WALTER L. BIERRING *

The National Board of Medical Examiners
J. STEWART RODMAN — ROBERT W. KEETON *

The American Board of Ophthalmology
DERRICK VAIL — EDWIN P. DUNPHY *

The American Board of Otolaryngology
LEROY A. SCHALL — DEAN M. LIERLE *

The American Board of Obstetrics and Gynecology
HERBERT E. SCHMITZ — ROBERT L. FAULKNER *

The American Board of Dermatology and Syphilology
DONALD M. PILLSBURY — GEORGE M. LEWIS *

The American Board of Pediatrics
LEE FORREST HILL — JOHN McK. MITCHELL *

The American Board of Psychiatry and Neurology
FRANCIS GERTY — ROLAND P. MACKAY

The American Board of Radiology
DOUGLAS QUICK — B. R. KIRKLIN *

The American Board of Orthopedic Surgery
CLARENCE H. HEYMAN — HAROLD A. SOFIELD *

The American Board of Urology
GILBERT J. THOMAS — HARRY CULVER *

The American Board of Internal Medicine
WALTER L. PALMER — HENRY M. THOMAS JR.*

The American Board of Pathology
ROBERT A. MOORE — WILLIAM B. WARTMAN *

The American Board of Surgery
WARREN H. COLE — JOHN B. FLICK *

The American Board of Anesthesiology
R. J. WHITACRE — CURTISS B. HICKCOX *

The American Board of Plastic Surgery
BRADFORD CANNON — WILLIAM A. HAMM *

The American Board of Neurological Surgery
FRANCIS GRANT — LEONARD T. FURLOW *

The American Board of Physical Medicine and Rehabilitation
ROBERT L. BENNETT — EARL C. ELKINS*

The American Board of Preventive Medicine
WILLIAM P. SHEPARD — ERNEST L. STEBBINS *

The American Board of Proctology
WALTER A. FAUSLER — LOUIS A. BUIE *

Officers and Committees—1953

ROBERT A. MOORE, American Board of Pathology, President.
WARREN H. COLE, American Board of Surgery, Vice President.
B. R. KIRKLIN, American Board of Radiology, Secretary-Treasurer

MEMBERS OF THE EXECUTIVE COMMITTEE
- Term to expire in 1954: WALTER L. PALMER, American Board of Internal Medicine
- Term to expire in 1955: ROBIN C. BUERKI, American Hospital Association

COMMITTEE ON STANDARDS AND EXAMINATIONS
- ROBERT L. FAULKNER, American Board of Obstetrics and Gynecology, Chairman
- HAROLD A. SOFIELD, American Board of Orthopedic Surgery
- LOUIS A. BUIE, American Board of Proctology

COMMITTEE ON AUDIT AND FINANCE
- FRANCIS GERTY, American Board of Psychiatry and Neurology, Chairman
- WALTER L. PALMER, American Board of Internal Medicine

REPRESENTATIVES ON ADVISORY COUNCIL ON MEDICAL EDUCATION
- WARREN H. COLE, American Board of Surgery
- ERNEST L. STEBBINS, American Board of Preventive Medicine

---

* Corresponding member.

Examining and certifying boards in 19 specialties have been approved by the Council on Medical Education and Hospitals of the American Medical Association and the Advisory Board for Medical Specialties on the basis of minimal standards governing accreditation of specialty boards as formulated by the Council.

The primary purposes of the boards are (1) to conduct investigations and examinations to determine the competence of voluntary candidates for certificates issued by the respective boards, (2) to grant and issue certificates of qualification to candidates successful in demonstrating their proficiency, (3) to stimulate the development of adequate training facilities, (4) to aid in evaluating residencies and fellowships under consideration by the Council on Medical Education and Hospitals of the American Medical Association, and (5) to advise physicians desiring certification as to the course of study and training to be pursued.

The boards are in no sense educational institutions, and the certificate of a board is not to be considered a degree. It does not confer on any person legal qualifications, privileges, or a license to practice medicine or a specialty. The boards do not purport in any way to interfere with or limit the professional activities of any licensed physician, nor do they desire to interfere with any practitioners of medicine in any of their regular or legitimate duties.

Two boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology, and pulmonary diseases. The American Board of Pediatrics certifies in allergy. Certification in the primary field is a requirement for certification in the subspecialties. The Board of Thoracic Surgery, which is organized as an affiliate board of the American Board of Surgery, requires certification in surgery as a prerequisite to certification in thoracic surgery.

Certificates in special divisions of their specialty are conferred by five boards. The American Board of Obstetrics and Gynecology will issue certificates in obstetrics or gynecology only. The American Board of Otolaryngology grants a limited certificate in endoscopy. The American Board of Pathology issues certificates in pathologic anatomy, clinical pathology, a combination of these two fields, pathologic anatomy and clinical microbiology, clinical microbiology and clinical chemistry, clinical bacteriology, neuropathology, and clinical microbiology. The American Board of Psychiatry and Neurology issues separate certificates in psychiatry and in neurology, or a combined certificate for those qualified in both fields. This board also issues supplementary certificates in psychiatry and in neurology. The American Board of Radiology issues certificates in radiology, roentgenology, therapeutic radiology, therapeutic roentgenology, diagnostic roentgenology, radium therapy, radiological physics, x-ray and radium physics, and medical nuclear physics.

Each of the boards has published a booklet containing a list of its officers and a brief statement of its organization, purposes, and the qualifications that determine eligibility for certification. A summary of the current data pertaining to each board and the names of its officers are reproduced in the following pages.

There is included in this section a specific statement from each of the boards regarding allowances of credit for service in the armed forces during the present emergency. A résumé of medical education and national defense was published in the Education Number of THE JOURNAL.[1]

Table 1 contains a list of the approved specialty boards, the year of their activation, the number of certificates issued prior to July 1, 1952, and the total number of candidates certified to June 30, 1953. Figures are also given in these two categories showing the numbers certified in the subspecialties and finally the available figures pertaining to special certification by the boards in obstetrics and gynecology, otolaryngology, pathology, psychiatry and neurology, and radiology.

On July 1, 1952, there were 48,464 physicians certified by the 19 boards. During the year July 1, 1952, to June 30, 1953, a total of 4,022 certificates were issued. Up to this latter date 52,486 physicians have been certified.

On July 1, 1952, a total of 1,255 certificates in subspecialties had been awarded. An additional 53 were awarded in the ensuing year, bringing the total number of certificates issued in the subspecialties to 1,308 on June 30, 1953. Prior to July 1, 1952, the five boards mentioned had issued 9,005 special certificates. During the year ending June 30, 1953, 843 special certificates were issued, bringing the total number awarded to that date to 9,848.

The number of specialists certified each year during the past 14 years by all boards and the cumulative totals are recorded in table 2. Up to June 30, 1953, a total of 52,486 certificates were issued. This does not represent the number of living specialists, but the total number of certificates issued.

The sixth edition of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties, published in 1953 by the A. N. Marquis Company, Chicago, contains biographic information on the educational background of each living specialist, including those retired from practice, certified by an American board.

CREDIT FOR MILITARY SERVICE

At the suggestion of the Joint Committee on Medical Education in Time of National Emergency, the Advisory Board for Medical Specialties conducted a survey to determine the amount of credit for service in the armed forces during the present emergency that would be given toward specialty board certification. The inquiry addressed to the boards contained the following questions:

> Will your specialty board give preference to those candidates wishing to be examined before going overseas or entering military service?
>
> How much, if any, credit toward your training and/or experience requirements will your board allow candidates while in military service?

---

* Included in totals for American Board of Surgery.
† Independent board established in 1949.

In reply to the first question all boards answered in the affirmative. The specialty boards have not lowered their requirements because of the military emergency, but all boards have indicated they will grant some credit for military service. The specialty boards have indicated such allowances as follows:

Anesthesiology.—No formal training credit is granted for military service unless the physician is assigned to a service hospital with an approved residency training program. Practice time will, however, be granted for military service if the physician is assigned to the anesthesia service.

Dermatology and Syphilology.—Full-time dermatological military service may be credited in part, at the discretion of the board, toward the required three years of training, provided a significant portion of formal training was completed before entering military service. However, at least one year of the required three years' training, including instruction in the fundamental subjects deemed essential for an adequate dermatological education, must be spent in an institution approved for a three-year training program by the board and the Council on Medical Education and Hospitals of the American Medical Association. Dermatological work not credited as training may satisfy part or all of the required two years' additional experience, the amount of credit depending on the circumstances.

TABLE 2.—*Annual Specialty Board Certification, 1940-1953*

Year (Ended March)	Number of Board in Existence	Number Certified	Cumulated Totals
1940	14	.....	15,853
1941	15	2,085	17,938
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,424	28,496
1948	16	3,002	31,498
1949 (June 30)	19*	4,479	35,977
1950 (June 30)	19	3,827	39,804
1951 (June 30)	19	4,552	44,346
1952 (June 30)	19	4,118	48,464
1953 (June 30)	19	4,022	52,486

* One board, the American Board of Proctology, did not certify any candidates during this period.

Internal Medicine.—Active duty subsequent to June 1, 1950, may be applied for not more than one year of residency or practice credit, regardless of assignment. Service beyond one year may only be applied as practice credit on the certification of former chiefs of service, unless the candidate served officially as a resident in a service approved for residency in internal medicine while there.

Neurological Surgery.—Credit will be allowed toward training requirement if candidate is assigned to neurological surgery in a military hospital; also, credit will be allowed for practice requirement if assigned to neurological surgery.

Obstetrics and Gynecology.—Credit will be given for time spent in an obstetric-gynecological service in an Army or a Navy hospital under supervision on the same basis as a preceptorship, if these departments are supervised by diplomates of the board or recognized obstetricians-gynecologists. Full residency credit may be obtained if such hospital is approved for residency training. The board will review and give consideration to each individual case. Special request must be made for such credits.

Ophthalmology.—No stated credit. Each case is decided according to the time the candidate has spent assigned to a military hospital in ophthalmology and on other factors.

Orthopedic Surgery.—Up to one year of residency credit is given. Each case is determined on its own merits.

Otolaryngology.—Credit is given but each case is determined on its own merits.

Pathology.—Allows liberal credit toward training when assigned to department of pathology but candidates must first have had a minimum of one year residency in an approved civilian department of pathology.

Pediatrics.—One year of credit, regardless of assignment, towards two year practice requirement.

Physical Medicine and Rehabilitation.—Maximum of one year credit in related field; full credit if in the specialty.

Plastic Surgery.—Credit given on individual basis, considered on candidate's merits.

Preventive Medicine.—Credit for training and experience in public health or aviation medicine while in military service will be considered on an individual basis, depending on the type of service.

Proctology.—One year in fulfillment of either general surgical or proctologic requirements.

Psychiatry and Neurology.—Training and experience credit toward requirements for examination will be granted for military duty in the present emergency under certain conditions. This policy relates to active military medical duty since July 1, 1950. One year of training credit will be granted for one year spent in full time psychiatric and/or neurological duties. Additional training credit will be granted for that amount of time spent in approved training programs. Experience credit will be granted for any remaining time spent in full time psychiatric and/or neurological assignments. Double credit will not be granted for any single period of time.

Radiology.—Maximum of one year's credit if assigned to full time radiological duties.

Surgery.—If a candidate has served in a government hospital or hospitals fully approved for residency training, such training will be acceptable to the board. Military credit may be extended to those candidates who have served in nonapproved hospitals provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical material and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the board. Any credit extended in the latter category will be considered preceptorship credit and not residency credit.

Thoracic Surgery.—Credit for military service will be decided on an individual basis.

Urology.—No credit for training but credit for one year of practice requirement if training was complete when entering service.

Medical Officer's Professional Training Record.—The Surgeons General of the armed services have distributed a booklet prepared with the assistance of the Council and the Advisory Board for Medical Specialties which is designed to help prospective candidates for certification to maintain an accurate account of work done in the military service. This record will constitute part of the credentials to be submitted to the board on application for certification. The booklet has been printed by the Office of the Secretary of Defense and is distributed by the offices of the Surgeons General to the personnel of their departments. It is highly important that prospective applicants obtain a copy of the "Medical Officer's Professional Training Record" and that they submit their credentials for evaluation by the respective specialty board.

AMERICAN BOARD OF ANESTHESIOLOGY

Board of Directors

Charles F. McCuskey, President, Los Angeles.
Rolland J. Whitacre, Vice President, East Cleveland.
Donald L. Burdick, New York.
Stuart C. Cullen, Iowa City.
Frederick P. Haugen, Portland, Ore.
*John S. Lundy, Rochester, Minn.
Meyer Saklad, Providence, R. I.
Harvey C. Slocum, Galveston, Tex.
Scott M. Smith, Salt Lake City.
Edward B. Tuohy, La Canada, Calif.
Curtiss B. Hickcox, *Secretary-Treasurer*, 80 Seymour St., Hartford 15, Conn.

Past Directors

*E. A. Rovenstine, New York.
Henry S. Ruth, Haverford, Pa.
*H. Boyd Stewart, Tulsa, Okla.
*Ralph M. Tovell, Hartford, Conn.
*Ralph M. Waters, Orlando, Fla.
John W. Winter, San Antonio, Tex.
*Paul M. Wood, New York.
*Philip D. Woodbridge, Greenfield, Mass.
*T. Drysdale Buchanan (deceased).

---

*Past Presidents.

CERTIFICATION

1. *Method of Making Application.*—Application for certification may be made after a physician has completed one year of approved training. Application must be made to the secretary on a form prescribed by the board, procured only on written request of the applicant, and must be filed at least six months prior to the date of examination.

The secretary cannot make any eligibility rulings. These are made only by the entire board on recommendation of the appropriate committees after reviewing the candidate's formal application.

2. *Requirements.*

A. Each applicant before he shall become eligible for certification in anesthesiology, must:

1. Have graduated from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association (graduates of foreign medical schools not recognized by this council will only be eligible to take the board examinations after they successfully pass or are eligible to take the examination given by the National Board of Medical Examiners), and have completed an internship of not less than one year in a hospital approved by the same Council, or its equivalent.

2. Establish in a manner satisfactory to the board that:
    (a) He is a physician duly licensed by law to practice medicine.
    (b) He is of high ethical and professional standing.
    (c) He has received adequate special training in anesthesiology.

3. Submit proof to the board that he has limited his practice to anesthesiology as a specialty for five calendar years of which at least two have been in formal clinical training approved by the board, and that he intends to continue to limit his practice to anesthesiology.

4. Be a member in good standing in the American Medical Association, the state and local county medical society or comparable national medical society approved by this board. He must be a member in good standing of the American Society of Anesthesiologists, Inc.

5. Prove to the satisfaction of the board by such written, survey, oral and practical examinations as the board may prescribe that he is qualified to practice anesthesiology.

6. Personally prepare such case history abstracts of personally conducted procedures pertaining to anesthesiology as the board may specify.

B. Each applicant shall be classified for the purpose of examination and shall be examined in such a manner and under such rules as the board may prescribe.

3. *Examinations are conducted as follows:*

A. Written Examination: Eligible applicants may take this examination on completion of two years of clinical training approved by the board. Written examinations are held annually in approximately twelve locations throughout the United States on the third Friday in July. Written examinations are of the multiple choice type covering the following subjects: anatomy, chemistry and physics, pharmacology, pathology and physiology. A passing grade, as determined by the board, is required.

B. Survey Examination: Started in 1949 this examination is conducted by one or more diplomates of the board who visit the applicant in his own locality to observe him in the practice of anesthesiology. The examiner may interview other individuals in the community to determine whether the candidate is of high ethical and professional standing. This examination is conducted on completion of four years limited to anesthesiology (including two years of approved clinical training).

C. Oral Examination: On completion of a favorable survey examination and five years limitation of practice to anesthesiology an applicant is eligible to appear for oral examination. However, at least six months must elapse between the written and oral examination. Examinations are conducted semi-annually, in April and October. Examiners consist of directors of the board plus diplomates who assist as associate examiners. Oral examinations cover all phases of anesthesiology as do the written examinations; emphasis, however, is placed on clinical application.

D. Practical Examination: At the discretion of the board practical demonstrations may be required of the management of the candidate's clinical practice in his local surroundings. This may include inspection of clinical records, reports of departmental activities, library facilities, available apparatus and demonstrations of application of anesthetic agents, methods and all technics included in anesthesiology. The candidate will also be appraised as to whether he is of high ethical and moral standing in his community.

Applicants are entitled to three consecutive opportunities at yearly intervals to satisfactorily complete the written examination. This three year period begins on the date an applicant is first declared eligible for the written examination.

Applicants are entitled to no more than two survey examinations. Should the first survey report be declared unfavorable a candidate will not be permitted to appear for the oral examination until a favorable report is received. At least one year must elapse before a resurvey examination is given.

Oral examinations are given at six month intervals. An applicant is entitled to one oral examination each year for a three year period. In the event that a candidate fails an oral examination, at least 12 months must elapse before he may reappear for the oral examination. The three year period begins on the date an applicant is first declared eligible for the oral examination.

Failure to take an examination constitutes an opportunity just as much as failure to pass an examination. Applicants who fail to exercise the privilege of written or oral examination and/or who fail to pass any part of the written or oral examination within the three year periods will be required to file a new application under the current rules and regulations, pay a new application fee, and submit to both written and oral examination.

A fee of $15.00 will be charged for each reexamination for candidates who file application January 1, 1950 or later. The board may, however, at its discretion deny a candidate the privilege of reexamination.

The board reserves the right to limit the number of candidates to be admitted to any examination.

REAPPLICATIONS

Applicants whose original applications were declared void through failure to take the examination will be required to file a new application under the current rules and regulations, pay a new application fee, and submit to both written and oral examination. Applicants whose original applications were declared void through failure to pass the examination must submit proof of an additional year of approved training before their re-applications will be considered. This re-application will be considered under the current rules and regulations, and the applicant must pay a new application fee and submit to both written and oral examination.

FEE

The fee shall be $125. At least $50 shall be paid on filing the application, of which sum $35 shall be returned if the candidate is not accepted for examination. The remainder ($75) shall be paid before taking the examination.

The board is a nonprofit organization. The fees for examination and certification have been computed on a basis of cost of maintaining an administrative office and conducting examinations. The board reserves the right to increase the fee when necessary.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

Donald M. Pillsbury, President, Philadelphia.
Nelson P. Anderson, Vice President, Los Angeles.
J. Lamar Callaway, Durham, N. C.
Marcus R. Caro, Chicago.
Anthony C. Cipollaro, New York.
Arthur C. Curtis, Ann Arbor, Mich.
John H. Lamb, Oklahoma City.
Francis W. Lynch, St. Paul.
George M. Lewis, Secretary-Treasurer, New York.
Miss Janet Newkirk, Executive Secretary, 66 East 66th Street, New York 21.

ADVISORY MEMBERS

Harold N. Cole, Cleveland.
Charles C. Dennie, Kansas City, Mo.
Howard Fox, New York.
C. Guy Lane, Boston.
George M. MacKee, Stamford, Conn.
Henry E. Michelson, Minneapolis.
Paul A. O'Leary, Rochester, Minn.
Francis E. Senear, Chicago.
Bedford Shelmire, Dallas, Tex.
Arthur W. Stillians, Chicago.
Fred D. Weidman, Philadelphia.

PURPOSES

The board was established primarily to determine the competence of physicians who specialize in dermatology and syphilology. It has therefore established minimum standards of education and training, examines applicants and certifies properly qualified specialists in this field, prepares lists of those qualified and arranges for the publication of such lists. Because of its interest also in the fulfillment of these standards, the board has a keen interest in the development of adequate training facilities, investigates institutions and individuals planning to train specialists, and lends its aid to the approval of those institutions and individuals offering adequate training in the specialty. The board, in addition, will always be glad to advise physicians desiring to enter this special field of medicine.

The board assumes the responsibility of determining the standards of knowledge to be acquired, but upon the candidate rests the responsibility of acquiring the knowledge to fulfill these standards.

REQUIREMENTS FOR ELIGIBILITY FOR EXAMINATION

I. General Requirements

1. High ethical and professional standing.

2. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

3. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council. During three years of the second World War, internships of nine months only were the rule. These were voted to fulfil the internship requirement. However, all internships completed on July 1, 1947 or thereafter must be of twelve months duration or longer.

4. A state license to practice medicine issued by endorsement of the certificate of the National Board of Medical Examiners or following examination.

5. Citizenship in the United States or citizenship—meaning native citizens—in Canada or Cuba.

II. Special Requirements

A period of study, after the internship, of not less than three years. One month or less in each of the three years may be spent as a vacation at the discretion of the chief of service. Vacations may not be postponed from one year to another, in other words, *they are not cumulative.* Candidates will not be eligible until three full years have elapsed since the beginning of training. This training may be obtained as resident, fellow or graduate student in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology. This period of specialized training shall include:

(*a*) At least 12 months in an institution approved for three year training (less one month for vacation).

(*b*) Graduate training in the basic medical sciences which are necessary for the proper understanding and treatment of the diseases involved in this specialty. This training is incorporated in the curriculum of the institutions approved for three years.

Instruction in the following fundamental subjects as related to the skin is deemed advisable by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and materia medica, and physics of physical therapy.

(*c*) Carefully supervised clinical and laboratory experience in the specialty.

(*d*) Annual examinations or other appraisal by the chief of service in the clinical, laboratory and public health aspects of dermatology and syphilology.

Training must be completed within a span of five years.

CREDIT FOR MILITARY SERVICE

1. All students in training who have served as physicians in the Army, Navy, or U. S. Public Health Service may submit a supplementary application, obtainable from the executive secretary, for evaluation of possible credit towards experience. Since the amount of credit must be agreed upon by members of a committee living in different, often widely separated cities, several months may be required before a decision can be rendered. The student is then notified.

2. Full-time dermatologic military service may be credited in part, at the discretion of the board, toward the required three years of training, provided a significant portion of approved formal training had been completed before induction. However, at least one year of the required three years' training, including instruction in the fundamental subjects deemed essential for an adequate dermatologic education, must be spent in an institution approved for a three-year training program by the board and by the Council on Medical Education and Hospitals of the American Medical Association.

The board strongly urges that the candidate supplement his military experiences by a further period of systematic and supervised dermatologic training before the examination.

3. Dermatologic work in the armed forces not credited as training may satisfy part or all of the required two years' additional dermatologic experience, the amount of credit depending on the circumstances.

Note: The supplementary application is not obligatory, but if submitted it must be done *prior to or at the time of filing application for examination.* Supplementary applications will not be considered until the preliminary registration has been filed.

PRECEPTORSHIP TRAINING

Candidates may spend up to two years of their training under the direction of a diplomate of the board, who has also been approved as a preceptor by the board. Not more than one half of each training day may be spent in the office of the preceptor; during the other half day, supervised work must be performed in an approved institution. The program which the student follows must conform to a schedule which an approved preceptor files with the board. The preceptor and the chief of service of the institution which the candidate attends are jointly responsible for the training received by the student. Preceptorship training may be taken during any two of the years of training. Time spent with an instructor who has not been approved by the board may sometimes count as experience but not as training. A list of approved preceptors is available from the executive secretary.

PRECEPTORS

A dermatologist who wishes to be considered for the responsible position of preceptor must fulfill the following requirements: he must be (1) a diplomate of the board of at least 5 years' standing; (2) a recognized teacher; (3) an active member or professor emeritus of the dermatologic staff of an institution approved for training by the board; and (4) recommended as suitable by the chief of staff of that institution. He must be willing to submit regular reports of the student's training on forms supplied by the board.

In order to be considered by the board, a specialist so qualified should make application to the secretary. Forms will be supplied on which the physical equipment and other facilities of the office are detailed, and on which the proposed plan of instruction is outlined, including the required institutional training. The application will then be acted upon at the next meeting of the board.

The status of a preceptee is not to be confused with that of an office associate.

PRELIMINARY REGISTRATION

All students beginning graduate training should write for the booklet of information, with whose contents they are expected to make themselves familiar, and for the preliminary registration form which must be filled out in detail and filed with the board at that time, even though plans may not be complete. This will enable the board to detect any deficiencies in basic qualifications or in the contemplated plan of training. No fee is involved.

ESTIMATES OF STATUS

Many candidates write the secretary outlining their training and asking for an estimate of their status and the further training required. The board's requirements are published to provide this information, and any candidate should be able to estimate his eligibility after studying these requirements. Individual officers or members of the board cannot and will not make such estimates. They will be made only by the Committee on Requirements, upon submission of the application for examination and the payment of the $25 registration fee which must accompany it. Personal interviews with officers of the board should not be requested at any time.

APPLICATION FOR EXAMINATION

In order that the Committee on Requirements may appraise carefully the qualifications of candidates, application must be made on the special blank, which may be obtained from the executive secretary. Applications should be filed early in order, to obtain full advantage of the loan sets of histopathologic slides available from the Armed Forces Institute of Pathology in Washington.

Applications must be filed before the closing date regularly published in the Examinations and Licensure section of THE JOURNAL. Dates of examinations are also published here. The completed application should be sent to the executive secretary, together with the required photographs and a *registration* fee of $25, which will not be refunded under any circumstances. No application will be considered until this fee is received. An *examination* fee of $75 is payable when the candidate is notified that his application is acceptable to the board. The total fee of $100 has been carefully computed and is used entirely for administrative purposes. Members for the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

All applicants are now required to take and pass a written examination before they are eligible for the oral test, in whole or in part. The written examination on clinical, basic science and laboratory subjects will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination.

All applicants are also required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital, where individual cases and clinical dermatology will be discussed with each candidate, as well as various subjects related to the skin such as histopathology, mycology, allergy and physics of physical therapy. The board reserves the right to add to this list other subjects within the field of dermatology and syphilology.

A candidate for a certificate may take his examination the next time it is given after he has completed three full years of training in the specialty, provided he makes application before the quota for that session is filled; this provision does not affect the regulations about the issuance of the certificate. (See Certificates.)

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will try especially to ascertain the breadth of his knowledge in the basic, as well as the clinical aspects of cutaneous medicine, to test his familiarity with the recent literature of dermatology and syphilology and to ascertain his general qualifications as a specialist in this branch of medicine.

Candidates who have signified their intention of taking the examination and who fail to appear at the scheduled time or who cancel their appointment after the sending of the final notice, shall forfeit the fee for the examination.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

The board's records are confidential throughout. Examination marks will not be divulged to the applicant or to anyone else. The findings of the board are subject to its discretion and are final. Examination will be given only on this understanding.

REEXAMINATIONS

If the candidate fails or is conditioned in an examination he will be considered eligible for a second examination without further formal application, but must give at least 60 days' notice of his wish to do so. His acceptance for a particular examination will be dependent on the number of candidates already on the roster. As the cost of examining a candidate is approximately the same each time, whether the whole or only a part of the examination is taken, a reexamination fee of $50 will be charged. After a second failure to complete the examination successfully, the candidate must file a new application and pay the initial examination fee of $75.

If a candidate who has failed or been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of $75 before he can be reexamined.

After Dec. 31, 1953, if a candidate has failed to complete successfully all or part of the examination on two occasions, he will be required to submit proof of at least six months' additional training in an institution approved for three years before being eligible for further examination.

CERTIFICATES

A certificate will not be issued until the successful candidate has completed at least five years of dermatologic training and experience. The granting of this certificate by the board indicates that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

Certificates will be issued only to members of the American Medical Association or to members of a similar society recognized as having the same purpose. A candidate does not become a diplomate until this requirement has been fulfilled.

Medical schools, hospitals, physicians, the Army, the Navy, the Public Health Service, and various government and philanthropic agencies, as well as the lay public, all utilize the certificate from this board as proof of adequate preparation in the field of dermatology and syphilology and of fitness of candidates for positions under their control. For this purpose, lists of those holding certificates from the board are available for inspection and are published from time to time in the Directory of Medical Specialists. Diplomates are identified in the Directory of the American Medical Association.

A certificate granted by this board does not of itself confer or purport to confer any degree or legal qualifications, privileges or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to raise the standards of practice of dermatology and syphilology by encouraging improvement in the opportunities for and quality of training for specialists in this field of medicine, and to certify as specialists those who voluntarily comply with the requirements of the board.

Certificates will be issued only to physicians practicing in the United States and its possessions, in Canada and in Cuba.

A diplomate is required to confine his practice to dermatology and syphilology except for such emergency programs as have been approved in principle by the American Medical Association.

The names of all diplomates of the American Board of Dermatology and Syphilology are supplied promptly to the Directory of Medical Specialists, published by the A. N. Marquis Company, 210 East Ohio Street, Chicago, Ill.

ADVERTISING

It is not considered good form for a diplomate to advertise to the lay public the board's recognition of his training and ability. He should not use commercial methods and avenues. It is proper to include a statement or phrase such as "Diplomate of the American Board of Dermatology and Syphilology" in sending out announcement cards when opening an office or in inserts after the author's name in a medical publication when the association with a hospital, medical school, or medical society is also mentioned. If the diplomate is in doubt, it would be well to consult the board before placing his good name in jeopardy.

PUBLICATIONS OF THE BOARD

1. Booklet of Information. All candidates should request a copy and be familiar with its contents.

2. Booklet of Opportunities for Prospective Graduate Students, containing details of the training programs in the approved institutions. (Latest edition—1948.) A check or money order for $1.00 should accompany request for a copy. Please do not send stamps.

3. Syllabus of Graduate Training (presently out of print, but in process of revision).

(*a*) To inform the candidate of the field to be covered in his preparation.

(*b*) To aid the medical schools and the dermatology departments of medical schools and hospitals by outlining the scope of teaching deemed advisable for specialization in dermatology and syphilology.

RESPONSIBILITIES OF THE BOARD

The major object of the board is to pass judgment on the competence of internists who desire certification—not to determine who shall or shall not practice internal medicine as a specialty.

The American Board of Internal Medicine is not concerned with any mechanism which gains special privileges or specific recognition for those physicians who have been certified in internal medicine. It has never been the intent of the board to define requirements for membership on the staffs of hospitals.

The board endorses completely the stand of the American Board of Surgery which "specifically disclaims interest in or recognition of differential emoluments that may be based on certification."

REQUIREMENTS FOR ADMISSION TO EXAMINATION AND CERTIFICATION

Each applicant for certification by this board must satisfy the qualifications listed below: (I) General Qualifications A, B, C, D, (II) Professional Qualifications A, B, C, D. For exceptions to the requirements C and D under Professional Qualification see paragraph G.

I. General Qualifications

A. All candidates must be citizens of the United States or Canada.

B. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

C. All candidates must be active members in good standing in their county and state medical societies in their state of legal residence. Under unusual and exceptional circumstances the board reserves the privilege of modifying this requirement. (This ruling shall not apply to commissioned officers of the United States regular Army, or Air Force, or Navy, or United States Public Health Service or to full-time staff members [physicians] of the Veterans Administration who are otherwise Service Fellows of the American Medical Association.)

D. Canadian citizens must be active members of the Canadian Medical Association before admission to examination.

II. Professional Qualifications

A. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.

B. Satisfactory completion of an approved internship of not less than twelve months.[1]

C. Residency or fellowship approved by the Council on Medical Education and Hospitals of the American Medical Association in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph D.

Plan A: A residency or fellowship in internal medicine for a period of not less than three years in a hospital or other institution approved by the Council on Medical Education and Hospitals of the American Medical Association for residency or fellowship in internal medicine. In such instances in which a resident's nominal status differs from that of the other hospital residents, he must furnish the board with certification by the chief of the medical service and the medical director of the hospital that he actually performed the full duties of a resident as a bona fide member of the residency program. In addition, two years of practice of clinical internal medicine will be required. The board will accept the following equivalents as satisfying one year only of the three years of residency or fellowship to which this paragraph refers. (Two years must be in the field of general internal medicine.)

1. If twelve months of a two year approved internship in a hospital approved for residency training in internal medicine is limited to the medical service and medical specialties, credit will be granted for a first year of assistant residency. The remaining two years of residency training must be in the general field of internal medicine. Certification by the chief of the medical service as to compliance with this requirement must accompany application.

2. One year of approved residency in one of the medical specialties: allergy, cardiovascular disease, gastroenterology, hematology, pulmonary diseases, neurology, pediatrics, psychiatry, dermatology and syphilology.

3. One year of approved residency in pathology.

4. One year as a graduate student or as an instructor in an approved medical school on a full time basis in bacteriology, biochemistry, pathology, pharmacology, physiology or internal medicine.

5. An advanced degree in the medical sciences, provided the work has been done and degree obtained after graduation from medical school.

Note.—Graduate training credit for the time involved will be allowed candidates who take and satisfactorily complete postgraduate courses in internal medicine or the basic medical sciences provided by accredited medical schools on a full time basis. This ruling shall not apply to courses of less than three months' or more than twelve months' duration. A certificate of creditable performance, based in part, at least, on a formal examination on completion of the course, will be required.

Note.—Fellowship or research assignments not approved by the Council on Medical Education and Hospitals will require certification by the chief of service that such assignment was equivalent in graduate training opportunities and patient responsibilities to that of an approved residency in internal medicine or the subspecialties recognized by the board. This certification must be presented before application is filed.

---

[1] During the period in which the 9-9-9 program was in effect an approved internship of nine months will satisfy the requirement of twelve months. A residency of nine months is considered as nine months only.

D. *Alternate Training Plans:* The board firmly believes that the plan of intensive training prescribed above offers the best opportunity for a young physician to prepare himself to meet his responsibilities as a specialist in internal medicine. It is recognized, however, that capable individuals may accomplish the same result in a longer period of time during which the training is less intensive. The board realizes that a number of medical graduates cannot follow the shorter and more desirable plan either because suitable residencies are not available or, in some instances, because of personal and economic reasons. Accordingly, the board has modified its previous regulations governing eligibility for admission to examination. In doing so the board has not modified its standards of examination. It has liberalized its eligibility requirements for admission to examination by accepting half time formal training and the practice of internal medicine under favorable circumstances as to professional and hospital contacts, in lieu of part of the full time requirements. It is hoped that by this means exceptional individuals may acquire a knowledge of medicine and experience in its application sufficient to qualify for examination.

The program previously described (Plan A), which consists of three years of formal training in an approved residency or its equivalent, following internship, and two additional years in the practice of internal medicine, is recommended by the board. Variations in this program are now subject to the following regulations.

1. In all instances, one year of approved internship and one year of approved residency will be required, except as indicated under Plan G. The graduate training credit of one year heretofore granted as a result of active duty as a commissioned officer in the armed forces during the period beginning Dec. 7, 1941 and ending Jan. 1, 1947 and during the Korean emergency with effective date June 1, 1950, may not be applied in satisfaction of the one year of approved residency referred to in Plan D, E, or F unless the candidate's assignment is considered by the board to have been equivalent to an approved residency.

2. *Following one year of internship and two years of approved* residency,[2] the remaining requirements may be satisfied by:

Plan B; that is, by two years of half time formal training followed by two years of practice limited to internal medicine, or by

Plan C; that is, by five years of practice limited to internal medicine.

3. Following one year internship and one year of approved residency, the remaining requirements may be satisfied by:

Plan D[3]; that is, by four years of half time formal training followed by two years of practice limited to internal medicine; or by:

Plan E[3]; that is, by two years of half time formal training followed by five years of practice limited to internal medicine, or by:

Plan F; that is, by eight years of practice limited to internal medicine.

4. In every instance at least two years of practice in internal medicine must be included, but in instances in which four years of practice are substituted for one year of residency, only one additional year of practice will be required; when more than eight years of practice are substituted for two years of residency an additional year of practice will not be required.

5. Physicians who have practiced internal medicine for twelve years following an approved internship may qualify for the examinations without further training (Plan G).

Half time formal training under expanded plans B, D and E is defined as follows:

1. Half-time[3] as an instructor in clinical medicine in a recognized medical school in the United States or Canada.
2. Half-time[3] in a research fellowship sponsored by a recognized medical school in the United States or Canada.
3. Half-time[3] as *a graduate student in an approved graduate* medical school in the United States or Canada.

E. Practice Requirements: A period of not less than two years of practice in the general field of clinical internal medicine or in the more specialized branches of medicine. (See exceptions, Section D, paragraph 4.) This requirement may be satisfied by independent practice or in association with a recognized internist, following completion of requirements of formal training.

F. Graduates of Foreign Medical Schools: All candidates who are graduates of foreign medical schools must meet the following requirements as a minimum:

1. The physician must be a citizen of the United States.
2. The physician must furnish proof in the form, and to the extent deemed adequate by the Board that he (or she) has graduated from a medical school after completing a four year full time course in medicine.
3. The physician must have a license to practice in one or more states of the United States, and have been in active practice confined to internal medicine within the state of legal residence for at least two years.
4. The physician must be an active member of the county and state medical societies in which he (or she) has established legal residence.
5. Graduates of foreign medical schools prior to 1930 may qualify under the alternate plans of the board the same as graduates of approved medical schools in the United States.
6. Graduates of foreign schools in 1930 and thereafter must, in addition to all other requirements, satisfy the requirements of one year of approved internship, and three years of approved residency or fellowship in the United States, and at least two years of practice limited to the field of Internal Medicine in the United States. If, however, their school of graduation is "recognized" by the Council on Medical Education and Hospitals of the American Medical Association, graduates of foreign schools may qualify under the various plans of the board the same as graduates of approved Medical Schools in the United States.

G. Candidates Graduating Prior to 1937: The requirement of three years of graduate training will not apply to candidates graduating from approved medical schools in the United States and Canada in 1936 or previous thereto, provided such candidates have limited their work to the field of internal medicine for at least two years, and provided each candidate is recognized as an internist by his colleagues in his community.

H. "Preceptor Training": Preceptor type training is not recognized in satisfaction of any part of the three year requirement of formal graduate training.

I. Credit for service in the Armed Forces may be applied as follows:

1. Active duty prior to Jan. 1, 1947, may be applied for not more than one year as residency or practice credit, regardless of assignment. Service beyond one year may only be applied as practice credit on certification of former chiefs of service that assignments were in the field of Internal Medicine on a full time basis in the care of clinical patients, largely on one's own responsibility.
2. Active duty from Jan. 1, 1947, to June 1, 1950, may only be applied as practice on the certification of former chiefs of service as referred to in paragraph 1, unless the candidate served officially as a resident in a service approved for residency in internal medicine while there.
3. Active duty subsequent to June 1, 1950, may be applied for not more than one year of residency or practice credit, regardless of assignment. Service beyond one year may only be applied as practice credit on the certification of former chiefs of service as referred to in paragraph 1, unless the candidate served officially as a resident in a service approved for residency in internal medicine while there.

---

[2] For the second year of approved residency one of the equivalents described under C-Professional Qualifications may be substituted.

[3] Half time formal training is regarded as four hours per day for six days per week. It is required that half time formal training be verified by the head of the department. Verification must accompany application.

J. Graduates of the Chicago Medical School prior to approval by the Council on Medical Education and Hospitals of the American Medical Association and graduates of the Middlesex School of Medicine who received their degree in medicine prior to Jan. 1, 1951, and who have fulfilled all of the requirements set forth in *Section 2*, (Requirements for Admission to Examination and Certification), and an approved residency or fellowship of three years' duration (Plan A) and two years of practice in internal medicine may apply, and at the discretion of the Executive Committee or of the board be admitted to examination.

PRINCIPLES OF TRAINING

The American Board of Internal Medicine is interested in the fact that the candidate has embarked on a career of study voluntarily and has thereby expressed the desire to excel and to participate personally in the world's progress in medicine.

Preparation must be based on years of continuous thoughtful study. Therefore, in suggesting a program for those who wish advice, the board hopes to assist the candidates to avoid inferior and superficial programs which may lead to failure and disappointment in later years.

The board believes that all internists should have a sound fundamental knowledge of anatomy, bacteriology, biochemistry, pathology, pharmacology and physiology. Such knowledge is essential to the continued progress of any internist. The board anticipates that adequate training will be obtained in the basic sciences as applied to internal medicine during a formal three year residency program.

The board wishes to emphasize that time and training are but a means to the end of acquiring a broad knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge rests with the candidate. The responsibility of maintaining the standards of knowledge required for certification rests with the board.

APPLICATION

Candidates for examination must make their application on a prescribed form, which may be obtained from the office of the Executive Secretary-Treasurer.

The application must contain a record of the candidate's premedical and medical training as well as of internships, residencies, graduate study, hospital or dispensary staff appointments, teaching positions, service in the armed forces, membership in medical societies, medical papers published and the names of four well known internists to whom the board may write for professional and character reference.

The application must be accompanied by one recent, signed photograph of the candidate mounted on the application, and the registration and examination fee of $40.00 to cover the written examination, of which $25.00 will be refunded if the application is disapproved. Upon application for admission to the oral examination, an additional fee of $50.00 will be required. Upon notification of certification by the board, a further fee of $10.00 to cover cost of certification, will be required.

The requirements of graduate training and two years of practice in the field of internal medicine must be satisfied before a candidate is eligible to apply for admission.

METHOD OF EXAMINATION—WRITTEN AND ORAL

The examinations for certification by the board comprise two parts: Part I is written; Part II is clinical and is an oral examination. The written examination is held simultaneously in different sections of the United States and Canada. Effective Jan. 1, 1949, one written examination will be given each year. This examination will be held on the third Monday in October. This examination is divided into a morning and afternoon period for each of which three hours are allowed. The questions are of the multiple choice type, framed in such a manner as the board elects and designed to test the applicant's knowledge of applied physiology, anatomy, physiological chemistry, pathology, bacteriology and pharmacology as related to internal medicine, and his basic clinical acumen.

Candidates must pass the written examination before admission to the oral examination will be authorized. The oral examination is conducted under the direct supervision of the board. It is held near the time and place of the annual meetings of the American Medical Association and the American College of Physicians. The examination is conducted at the bedside of the patient. Each candidate is assigned two or more patients and is expected to be sufficiently familiar with whatever problems present themselves to satisfy the board of his clinical expertness.

Normally only two oral examinations are given each year. The board may, however, schedule special oral examinations if necessary. Announcements of all examinations will appear in the *Annals of Internal Medicine* and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Applications cannot be accepted until the schedule is announced in the publication referred to, and cannot be accepted after the closing date as announced.

REEXAMINATION—WRITTEN AND ORAL

1. Restrictions on the number of written examinations for which a candidate may apply have been waived. The interval between all written examinations will be not less than one year; however, the executive committee of the board may, in its discretion, require a longer period, or may for reasons it considers adequate, deny admission to reexamination. A fee of $15.00 is required for each written reexamination. The fee is due upon application for reexamination.

2. Restrictions on the number of oral examinations for which a candidate may apply have been waived. The interval between all oral examinations will be not less than one year, however, the executive committee of the board may in its discretion require a longer period or may for reasons it considers adequate, deny admission to reexaminations. A fee of $40.00 is required for each oral reexamination. The fee is due on application for reexamination.

3. This ruling does not make it mandatory for a candidate to repeat the examination within the specified time limit. Candidates may elect a longer interval in the case of both the written and oral examinations.

CANCELLATIONS

Effective July 1, 1949, any candidate who cancels his assignment for a written or an oral examination after Sept. 1 will be required to pay a special fee in the amount of $10.00 before a subsequent examination, unless his cancellation was due to a cause deemed adequate by the board to exempt him from such special fee. This provision becomes necessary because of the large number of cancellations after complete arrangements have been made, and the expense incident thereto.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the by-laws and shall be signed by the officers and members of the board and shall bear the official seal of the board.

Certificates of the board will be issued to candidates who have satisfactorily completed the written and oral examinations and have been found qualified by the board to practice the specialty of internal medicine. Specialty certification will be designated on the certificate, for those so certified.

SUBSPECIALTY BOARDS

Allergy, cardiovascular disease, gastroenterology and pulmonary diseases are recognized specialties.

Each subspecialty application is individually considered and acted on by the subspecialty board concerned. The candidate is not eligible for examination until his application has been approved by the subspecialty board concerned and confirmed by this board.

All candidates must pass the written and oral examinations in internal medicine before admission to examination in a specialty of medicine referred to. The specialty examinations are oral only and may be taken at any regularly scheduled oral examination subsequent to the candidate's certification in general medicine. Announcements of the oral examination will appear in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and the *Annals of Internal Medicine.*

Application forms will be forwarded on request to the office of the Executive Secretary-Treasurer and should be returned to his office when completed.

INFORMATION ON CERTIFICATION IN ALLERY BY THE AMERICAN BOARD OF INTERNAL MEDICINE

1. Two years, full time, including training both in allergy and internal medicine in an approved allergy clinic and hospital; or

2. One year, full time, including training in allergy and internal medicine in an approved allergy clinic and hospital, and two additional years of attendance and participation at least two half days weekly at an approved allergy clinic; or

3. Five years of attendance and participation at least two half days weekly at an approved allergy clinic; or

4. Twelve years in the practice of allergy after fulfilling the professional qualifications for certification in internal medicine, with evidence of sustained scientific interest.

5. All candidates who desire consideration in allergy must be certified in internal medicine before applying for admission to examination in allergy.

The candidate should be prepared for oral and clinical examination in the anatomy, pathology, physiology and biochemistry of reactions of hypersensitivity. This will include immunology, immunochemistry, atopy, allergy of infection, collagen disease, and experimental hypersensitivity. He should be proficient in clinical diagnosis, laboratory procedures, and in the treatment of allergic diseases. He should be familiar with the Physiology of respiration, especially as modified by bronchial asthma and pulmonary emphysema and with the pharmacology of drugs used.

NOTE.—Fellowship or research assignments not approved by the Council on Medical Education and Hospitals will require certification by the chief of service that such assignment was equivalent in graduate training opportunities and patient responsibilities to that of an approved residency in allergy recognized by the board. This certification must be presented before the application is filed.

RECOMMENDATIONS OF THE SUBSPECIALTY BOARD ON CARDIOVASCULAR DISEASE CONCERNING QUALIFICATIONS OF CANDIDATES FOR CERTIFICATION IN THIS SUBSPECIALTY

The applicant should be of good character and excellent standing in his community, as attested by letters from sponsors of known integrity.

The applicant should have reached a state of maturity, compatible with the acquisition of sufficient factual knowledge and experience to form a basis for sound judgment. The board believes that only exceptional individuals are sufficiently mature for this subspecialty before the age of thirty-five years or less than ten years after graduation from medical school.

The board will make exception to this general rule of admission to examination, under unusual circumstances, largely to avoid injustice to the younger men of outstanding ability.

The candidate must have given clear evidence of his deep and constant interest in cardiovascular disease over a period of years. The board is particularly interested in recommending for examination those applicants whose records indicate that their interest in cardiovascular disease will probably be sustained throughout life, and that their knowledge of the subject will constantly grow. Achievements in the field of research are regarded as evidence of such interest, but publication of articles or prolonged training in research work is not considered essential. Consideration will be given to the circumstances of each applicant's training and experience; those who have been in communities and institutions which offered excellent opportunities for contributions to the knowledge of cardiovascular disease will be expected to have made such contributions. Consideration will be given to the difference in experience of those whose opportunities for research have been more limited.

In most cases, it is deemed essential that the candidate, after thorough training in internal medicine, shall have received at least one full year of postgraduate education in cardiovascular disease, preferably under the guidance of a person known to be experienced and sound. Qualifications will be appraised by the Cardiovascular Board and admission of the applicant to the examination will be determined by a majority opinion of the board.

Every candidate admitted to the certifying examination in cardiovascular disease will be expected to possess specialized knowledge of the kind indicated below. This list is by no means complete; it is intended to indicate the nature, rather than the extent, of the knowledge every applicant should have. In terms of its scope it should be regarded as the minimum, not the maximum. Persons possessing special knowledge and training in peripheral vascular disease may be expected to have a higher standard required in the examination in that portion of the field than in the certain details of other branches of cardiology, and the converse may be similarly applied.

1. Full and accurate knowledge of the anatomy of the normal and diseased heart, including its relationships to the external chest and to the other mediastinal structures. A comprehensive anatomical knowledge of all important blood vessels including their aberrant locations.

2. A thorough knowledge of the normal and pathological physiology of the heart and peripheral circulation.

3. Detailed knowledge of the diagnostic signs which permit the recognition of all important diseases of the heart and blood vessels, such as arteriosclerosis, arteriosclerotic heart disease, syphilitic heart disease, rheumatic heart disease, constrictive pericarditis, auricular and ventricular septal defects, coronary thrombosis with myocardial infarction, thromboangitis obliterans, Raynaud's syndrome, coarctation of the aorta, aneurysm, patent ductus arteriosus, periarteritis nodosa and lymphedema.

4. Familiarity with the special methods used in the study of diseases of the heart and blood vessels. In the case of the heart, these include such technics as electrocardiography, roentgenography, catheterization and angiocardiography; in the case of vascular disease, such technics as the use of the oscillometer and thermocouple, arteriography, and venography, reflex vasodilatation, the cold pressor test, color changes with elevation, dependency, temperature, etc.

5. Accurate knowledge of the pathologic changes associated with the more important diseases of the heart and blood vessels, sufficient to enable the candidate correctly to evaluate the pathologic condition from gross specimens or microscopic sections.

6. Fairly extensive and detailed knowledge of the pharmacology relating to heart and blood vessels. This must include full knowledge of the important relationship of the autonomic nervous system both to the heart and to the peripheral vessels, and the effects of stimulation or paralysis of the various parts of the autonomic system by drugs or by surgical methods. The candidate should be intimately familiar with the use and effects of such important drugs as digitalis, quinidine, heparin, papaverine, epinephrine, dicumarol, penicillin, diuretics, sedatives, etc.

7. A sound understanding of the indications for conservative therapy, as well as for surgical procedures, in cardiac and peripheral vascular diseases (patency of the ductus arteriosus, arteriovenous anastomoses, constrictive pericarditis, scalenus, anticus syndrome, etc.).

In summary, it is the desire of the American Board of Internal Medicine and its Subspecialty Board in Cardiovascular Disease that physicians shall not be admitted to the certifying examinations unless they have exceptional qualifications as individuals and as experts in this subspecialty of medicine.

INFORMATION ON CERTIFICATION IN GASTROENTEROLOGY BY THE AMERICAN BOARD OF INTERNAL MEDICINE

A. Professional Standing

The candidate must have at least two letters from recognized internists or gastroenterologists, which must attest to the candidate's professional qualifications and ethical standing, whether he is specializing in gastroenterology and if not entirely, giving an opinion as to approximately how much of his work is devoted to it.

B. Education

1. The candidate must admit proof of adequately supervised training in the recognized gastroenterologic procedures, including gastric and hepatobiliary function tests, proctosigmoidoscopy and gastrointestinal roentgenology (film interpretation).

2. The candidate must present evidence of fulfilment of one of the following requirements:

- (*a*) Formal graduate course in gastroenterology, full time for at least eight months in a recognized institution.
- (*b*) Residency or fellowship for at least one year in gastroenterology under tutelage of a recognized specialist.
- (*c*) In the absence of (*a*) and (*b*), attendance and active participation in a ward service or in a gastrointestinal clinic, recognized in standing, for at least five years.

3. If requirements (*a*) or (*b*) under the above heading have been met, only three years of (*c*) will be required.

C. Practice

At least 60 per cent of the candidate's work must have been devoted to gastroenterology for at least three years before application.

INFORMATION ON CERTIFICATION IN PULMONARY DISEASES BY THE AMERICAN BOARD OF INTERNAL MEDICINE

I. Candidates for certification in pulmonary diseases shall fulfil the requirements of the American Board of Internal Medicine as to:

A. General qualifications.

B. Professional education.

C. Special training.

II. In addition to the General Requirements of the American Board of Internal Medicine, candidates shall:

A. Have completed special training period in pulmonary diseases to include at least a year's work in a sanatorium or hospital for tuberculosis and at least another year in the practice of pulmonary diseases in such an institution or in association with an older man competent in this field.

B. Submit an application to the Advisory Board in this specialty, which must be approved by all of the members of this board.

C. Pass the written and oral examination of the American Board of Internal Medicine.

D. Pass the oral and practical examination in pulmonary diseases.

AMERICAN BOARD OF NEUROLOGICAL SURGERY

Francis C. Grant, Chairman, Philadelphia.
R. Glen Spurling, Vice Chairman, Louisville.
Howard A. Brown, San Francisco.
Eldridge Campbell, Albany, N. Y.
William V. Cone, Montreal.
Franc Ingraham, Boston.
Eric Oldberg, Chicago.
Bronson S. Ray, New York.
A. Earl Walker, Baltimore.
James C. White, Boston.
Harry Wilkins, Oklahoma City.
Leonard T. Furlow, Secretary-Treasurer, Washington University Medical School, St. Louis.

General Qualifications

1. Moral and ethical standing in the profession satisfactory to the board of directors.

2. It shall be discretionary with the board to accept for examination candidates who have been in practice more than six years but whose formal training fails to meet the full requirements.

3. Properly qualified candidates who are permanent residents in and citizens of other countries and are legally qualified to practice medicine there, and who have received their training in neurological surgery in the United States of America or Canada may apply for certification by the American Board of Neurological Surgery.

4. A special certificate may be issued to foreign (not United States of America or Canadian citizens) candidates who have received their training in neurological surgery in the United States of America or Canada and who are returning to their own country at the end of their training period, upon passing successfully the regular examinations of this board, without completion of the requirement of two years in the practice of neurological surgery. This special certificate shall be appropriately identified to distinguish it from the regular certificate of this board.

Preliminary Professional Standing

1. Graduation from a medical school which is acceptable to the American Board of Neurological Surgery.

2. Completion of a surgical internship of not less than one year in a hospital acceptable to the board, or its equivalent in the opinion of the board. (A one year rotating internship does not satisfy this requirement.)

Special Training

A period of graduate study in a recognized graduate school of medicine of not less than three years beyond the year of general surgical training, or in an approved hospital or under a sponsorship acceptable to the American Board of Neurological Surgery for the training of neurological surgeons. The training in clinical neurological surgery must be progressive and not obtained during repeated short periods in a number of institutions. It is preferable that at least two years of this training be had in one institution, and the board will not ordinarily approve periods of training in clinical neurological surgery of less than one year

This period of special training shall be of such a character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to practice of neurological surgery will be required in the examination. The board will not credit periods of study limited to these basic sciences of longer than six months in fulfillment of this requirement of three years of special training.

Training in diagnostic neurology should be obtained either in correlation with training in neurological surgery or independently. The candidate will be required to pass an examination in this subject.

An additional period of not less than two years in the practice of neurological surgery.

The above represents only the minimum requirements of training for the practice of neurological surgery in the opinion of the board.

APPLICATIONS

An application on the official application blank in such form as may be adopted from time to time by the Board of Directors, in order to be considered at any meeting, must be in the hands of the secretary-treasurer of the board not less than sixty days before the date of such meeting.

The secretary-treasurer of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary-treasurer may deem desirable, after which he shall forward the application to the Committee on Credentials. This committee shall consider the application and other information available and notify the secretary-treasurer its recommendation whether or not the applicant is acceptable. The certification of a candidate shall be approved by a majority of the members of the entire board at any meeting held for such certification.

PAYMENT OF FEES

The fee for certification, with or without examination, shall be $100.

The candidate for examination on filing his application shall accompany it with an application fee of $25. When notified by the secretary-treasurer that he is eligible for examination he shall send the examination fee of $75 to the secretary-treasurer at least two weeks before the date of the examination. The application fee will be returned if the candidate is not accepted for examination.

REEXAMINATION

A candidate who has failed in one examination is eligible for reexamination in the subject, or subjects, in which he failed, within three years, on payment of a reexamination fee of $25. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Walter T. Dannreuther, President, New York.
F. Baynard Carter, Vice President, Durham, N. C.
Robert A. Kimbrough Jr., Vice President, Philadelphia.
Willard R. Cooke, Galveston, Texas.
Daniel G. Morton, Los Angeles.
John L. Parks, Washington, D. C.
Herbert E. Schmitz, Chicago.
Robert L. Faulkner, Secretary-Treasurer, 2105 Adelbert Road, Cleveland 6.
Lawrence M. Randall, Assistant Secretary, Rochester, Minn.

REQUIREMENTS

Each applicant before he may become eligible to receive such certificate of the board or other evidence of recognition:

1. Must have had conferred on him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

2. Must establish in a manner satisfactory to the Board of Directors that he is a physician duly licensed to practice medicine, and

   (*a*) that he is of high ethical and professional standing.

   (*b*) that he has received *at least minimal training* bilaterally, i. e., in both obstetrics and gynecology. Training in one branch only is no longer sufficient for qualification. The term "minimal training" as used here is at present defined as meaning at least one year of full time formal training, in the branch of either obstetrics or gynecology relegated to a minor role in a candidate's training program as related to his preference and plans for practice. The required total of formal training is three years.

   (*c*) that physicians otherwise qualified, who were graduated before Jan. 1, 1939 and whose required training was in obstetrics or gynecology alone, and who have confined their practice to obstetrics or gynecology for at least five years immediately prior to application be accepted for examination as candidates for certification in either obstetrics or gynecology. In all other respects requirements for eligibility remain the same as for those physicians graduated since 1939. Bilateral training is required. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless *of whether a candidate's practice is limited to one or* the other branch.

3. Must make application for investigation of his credentials and a survey of his character.

4. Must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so, except for possible military duties. Candidates will be accepted only if, on application or by the time of their examination, they have been in practice limited to the specialty for a minimal period of two years following completion of their specialty training. This change in requirements permits a qualified candidate to make his application in the second year of his post-training practice period. The sole exception to the two year limitation is practice for the Frontier Nursing Service, Inc., of Kentucky.

This board will not accept applicants for examination who are not full citizens of the United States or of Canada, though they may be residents of either country. Foreign born applicants must have been certified by either the National Board of Medical Examiners or licensed to practice medicine in the United States or Canada by a state or provincial board of licensure. Notarized statements, *not* original citizenship papers, must be furnished when the application is filed attesting to the fact of full citizenship in the United States or Canada, if the applicant is foreign born. Further, there will be required a probationary period of at least three years from the date of licensure in the practice of medicine in these countries before such a candidate may be admitted to examination.

Applicants who have been certified by one of the other American specialty examining boards will not be eligible for certification by this board until they have relinquished the certificate previously conferred. (In making application to this board for certification, applicants, for some time back, have agreed to revocation of their certification by this board if and when they apply for and receive certification by any other American board, except on special action to the contrary taken by the American Board of Obstetrics and Gynecology.)

The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology, except by special ruling when this is related to active military duty.

This board deprecates engagement in fields of practice other than that in which candidates profess to be specialists. The board does not exclude from examination, however, obstetricians-gynecologists who practice abdominal surgery and urology in the female because of the correlation of these activities. The sole exception to this provision is that it is permissible for candidates of the American Board of Obstetrics and Gynecology to participate in emergency care plans operated under the auspices of district, county, or state medical societies.

Military service or any other similar patriotic service, such as work with Selective Service boards, etc., have not been construed as nonlimitation of practice in violation of the board regulations. Officers (Regular or Reserves) certified by this board and on duty with "Family Dependent Services" are expected to be permitted to limit their work to the specialty, as in civilian life, and not to be engaged regularly in general or other practice.

The minimal requirements for all candidates will be uniform as follows:

1. Completion of at least one year intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. This need not be a general rotating internship, although this latter is preferred.

The board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation.

2. A minimum of seven years of training and practice after the intern year, to include at least three years of residency training in obstetrics-gynecology in approved institutions, or adequate preceptorship training. (See Section on Preceptorship Training.) Following completion of acceptable training two years of post-training practice limited to the specialty are required.

This leaves two other years in the total of eight years following graduation. During the early part of this period other training in branches, especially such as general abdominal surgery (see next paragraph), or in pathology, urology, internal medicine, or general practice is desirable and accredited on this total time period. The last two years of such an eight year period must be in practice limited to the specialty. (See paragraph 4 under Requirements.)

The Council on Medical Education and Hospitals of the American Medical Association listed for the first time in 1950 (*J. A. M. A.*, April 15, 1950, pages 1216, 1204-1211), 149 inspected and approved one year residencies in general surgery "as offering training in general surgery . . . in preparation for residencies in surgical specialties." Such residencies are recommended by this board as desirable additional preparation, particularly when they provide opportunities for training in abdominal surgery. (See Internship and Residency issues of The

JOURNAL for lists.) As noted above, such service may be included in the total minimal eight years required after graduation.

Post-training practice period may include full time medical school or other positions within the specialty, actual practice within the specialty as an assistant, associate, or independently.

Periods of residency in obstetrics-gynecology in excess of the required three years will not be accepted as a substitute for any part of the two required years of post-training practice except in the cases of men advancing from their residency training into and planning to remain in full time teaching positions in medical schools and their affiliated hospitals.

3. Basic science training should emphasize the relation of the basic sciences, anatomy, pathology, physiology, biochemistry and bacteriology, to the application of surgical principles which are fundamental in all branches of surgery. More especially, for this specialty there should be training in infertility, endocrinology, oncology, irradiation therapy, electrotherapy, psychosomatic medicine and other nonoperative methods of diagnosis and treatment. In addition, the candidate must understand and be trained in the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, protein and nitrogen balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, and so on.

Studies in the basic sciences may be integrated with the clinical work or may be given separately.

SPECIAL CREDITS AND RULINGS

The board conformed with the general acceleration in programs in medical education in that it will accept a period of nine "accelerated" months as an academic year in satisfying the requirement for each of three years of residency training. Such allowances can be made only for services during the wartime period of the official "accelerated program" and are not made for services before 1943 or after the discontinuance of this acceleration in 1946.

No formal graduate courses are required. If taken, credit will be limited to six months. Fellowships will be evaluated individually for credits by the Credentials Committee.

An applicant serving under military orders in an Army or a Navy hospital in an obstetrical-gynecological service under supervision will be given the same credit as if he were working under a preceptor, if these departments are supervised by diplomates of this board or recognized obstetricians-gynecologists. He may obtain full residency credit if such hospital is officially approved and listed for residency training in this specialty. The Credentials Committee of the board will review and give consideration to each individual case. Special request must be made for such credits.

A blank log-book entitled "Medical Officers Professional Training Record" is obtainable from the offices of the Surgeons General. This Record should be carefully kept and attested while in military service.

APPLICATION AND FEES

Application must be made on a special blank which will be furnished by the secretary's office and must be forwarded with the other required credentials and the application fee to the secretary's office not later than Oct. 1, 1953.

Candidates currently applying for admission to the examinations for certification are required to submit with their application a plain typewritten list of all patients admitted to the hospitals where they practice, for the year preceding their application or the year prior to their request for reopening of their application, with the diagnosis, pathological diagnosis, nature of treatment, and end result.

Candidates who have not had a minimum of three years' formal residency type of special training should utilize Preceptorship or Supplemental Training forms, obtainable from the office of the board, to submit in addition to the regular application form.

The application fee is $25 and is not returnable.

The examination fee is $100 and is payable when the candidate is notified of acceptance for examination. This fee is not returnable after the candidate has been officially accepted by the Credentials Committee and notified to report for examination.

If the candidate fails the Part II examination on his original application, he may exercise the privilege of one reexamination (see Examinations, Part II) but he will be required to pay a fee of $25 for such reexamination on making request that his application be reopened for this purpose. This ruling is effective on applications originally made after June 1, 1949.

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners and associate examiners serve as such without compensation other than actual expenses.

Many prospective candidates write the secretary's office outlining in their letters their training qualifications and asking informally if they are eligible, if this training has been sufficient and, if not, what is still lacking. Any candidate should be able to make a fair estimate of his eligibility after studying these requirements.

Individual officers and directors cannot and will not make any such estimates or rulings. These are made only by the Credentials Committee after reviewing such requests made on a special form provided for this purpose, and submitted to the secretary for an appraisal with the fee of $15 to cover clerical expenses involved. This form is designated the "Application for Appraisal of Incomplete Training."

Personal interviews cannot be granted by the secretary or other directors of the board unless requested by the board.

Appraisal of Incomplete Training forms should not be filed if Application for Certification has already been filed. This is unnecessary duplication.

All candidates must comply with the board regulations in effect for the year in which the examination is taken, regardless of when the original application was filed.

Applicants declared ineligible for admission to examination may request reopening of their applications within two years of the filing date without payment of an additional application fee. When a candidate requests that his application be reopened, he must supply the board with information to justify such further consideration. A request for the reopening of an application declared ineligible by reason of insufficient training, nonlimitation of practice or similar items may not be approved in less than two years, although application may be made as specified above to avoid payment of an additional fee. This approval time may be reduced under exceptional circumstances. The request must have adequate supporting evidence of additional training and experience to warrant reconsideration. Preceptorship or Supplemental Training blanks should be used for such reports, and these will be supplied on request.

After two ineligiblity or postponement rulings on any candidate's application, an entirely new application must be submitted (with or without fee, according to current requirements) in order to bring data down to date. The essential feature of this should be evidence of additional training and experience.

Applicants declared eligible but who fail to exercise the examination privilege within three years of the date of filing the application are required to file a new and current application and to pay a new application fee.

Candidates should offer as sponsors or references two diplomates of this board with whom they are presently in contact, rather than men under whom they served as residents only. It is required that sponsors be from the candidate's community and currently acquainted with the candidate and his ability in his practice of the specialty.

On notice of acceptance for admission to examination, examination fee is due and also case records which should be shipped by the candidate to the secretary's office as soon as possible and not later than the date of the Part I written examination.

The candidate should make immediate acknowledgment of his notice of acceptance, at which time he will notify the secretary's office approximately when to expect his case reports.

EXAMINATIONS

Part I examinations are scheduled annually for early in February. Grades cannot usually be mailed from the secretary's office until after April 1 following the examination. Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination which will be sent out from the board's office under sealed cover.

Special arrangement will be made through senior officers for conducting the written portion of the Part I examination for men in military service. Such candidates are requested to keep the secretary's office informed at all times of changes in their mailing addresses.

All applicants accepted for examination will be required to obtain a passing grade in both the written examination and a review of case reports (Part I), before becoming eligible for the oral-clinical and pathology examinations (Part II). The passing grade for the written xamination and case reports is 75 per cent. A candidate whose grade in either or both falls below 75 per cent is conditioned.

Reexamination for the removal of conditions in Part I may be taken after one year but within three years after the first failure, without payment of an additional fee.

Application for reexamination in Part I must be made by the candidate prior to Nov. 1 of any year.

Requests for reexamination in the written portion of Part I and requests for resubmission of case reports must be filed prior to Oct. 1, 1953.

Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year.

Requests for reexamination in Part II must be made prior to Feb. 1, 1954.

Candidates appearing for reexamination under a new application after two previous failures will not be required, if they have passed all or part of the Part I examinations on their first application, to repeat such examination items already successfully cleared.

PART I

Examination consists of:

1. A comprehensive written examination, conducted annually, including questions on both obstetrics and gynecology and related basic sciences. The written examination will be limited to a maximum period of three hours.

2. The filing, as early as possible, and not later than the date of the written examination, of 25 obstetrical and gynecological case reports, in condensed form. (See Sections on Case Reports.)

Results on case reports submitted for review prior to the written examination will be announced simultaneously with those of the latter; candidates who take the written examination but fail to submit case reports on or before the date of the written examination cannot be given the grade on the latter until their case reports have been received and graded.

PART II

The oral-clinical and pathology examinations given all candidates are conducted by the entire board and the associate examiners usually near the time and place of the annual meeting of one or more of the national societies represented on this board. Advance announcements of examination dates and place will be made in medical journals throughout the country. (Schedule for Chicago, May 10 to 17, 1954.)

Examination consists of:

1. Oral examination before two to four examiners.

An endeavor is made to adapt the details of the oral examination to each candidate's experience and practice. The examination is particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the related basic sciences, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

2. Pathology examination.

The candidate is expected to identify and to discuss several obstetrical and gynecological pathologic specimens and sections.

Examiners report orally on each candidate to the assembled board, after which the results of their investigations are considered jointly by the entire board and associate examiners. After a general consideration of the details of the candidate's oral and pathology examinations, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board of directors.

The final action of the board is based on the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examination.

When a candidate fails in Part II of the examination, he is not required to repeat Part I but is required to repeat Part II only. One reexamination may be taken within three years of the original examination and first failure without formal reapplication papers. Request for reopening of the candidate's original application must be filed with a reexamination fee of $25 (See Application and Fees). Application for reexamination in Part II must be made by the candidate prior to Feb. 1 of any year. Data regarding additional training or experience and medical school or hospital appointments acquired in the interim must be cited in the letter and verified on a Supplemental Training Form obtained from the office of the secretary of the board.

The reexamination fee will be effective only on original applications filed subsequent to the date of this announcement, namely, June 1, 1949.

The candidate may be allowed to reappear at the examination following the one failed by him. The board may, at its discretion, deny the candidate the privilege of reexamination. Requests for admission to reexamination must be accompanied by statements covering additional training, or opportunities for supervised clinical experience since the previous failure to justify such readmission.

Failure to exercise the privilege of reexamination within three years entails the filing of a new application with the usual application and examination fees.

After two failures in either Part I or Part II on the first application, the candidate may reapply with a new application and reapplication fee of $25 and reexamination fee of $100 and be readmitted to examinations once only. Exceptions to this ruling can be made only by action of the entire board of directors in annual session, usually to be based on evidence of additional training and experience sufficient to warrant such action.

CASE REPORTS

Case reports are to be sent by the candidate to the secretary as soon as possible after receiving notification of eligibility, and not later than the date of the Part I written examination.

In the case of candidates applying for unilateral certification, case reports must pertain to the branch for which application is made.

Twenty-five important obstetrical and gynecological case reports, in condensed form, are required. Five cases may concern major illnesses, not necessarily operative. These reports must include a variety of material rather than a number of reports of one type. Case reports from one residency's service shall not be more than five in number.

Men holding full time medical school faculty appointments may submit half their case records from this full time, nonprivate practice, but post-training service. (See Requirements.)

The candidate should prepare and maintain in his possession a carbon copy of his case records in case of possible loss in shipping.

These reports are not to be copies verbatim from hospital records, but should be in condensed form.

Evidence of adequate follow-up examination pertinent to each individual case must be submitted.

The candidate should submit *separate verified index lists, in duplicate* for each individual hospital at which operations were performed. All of these must be formally signed by the responsible hospital official (preferably the hospital superintendent), attesting in each instance that the candidate was the operator.

In the upper left-hand corner of each index sheet there should appear:

Candidate's Name; and Name and Address of Hospital.

The data for each patient should be tabulated horizontally, reading thus:

1. Sequence number of case report (1 to 25).

2. Whether patient was from the candidate's residency service or his own private or ward practice, as follows: "Res. Serv." or "Own Practice." *All records failing to have this information will not be considered acceptable.*

3. Patient's name or identifying initials, age, parity.

4. Date of patient's admission and hospital admission number.

5. Date of patient's operation.

6. Date of patient's discharge.
7. Dates of follow-up examinations.

At the foot of each index sheet should be placed the attested statement of the hospital official, referred to above. This statement should read as follows:

This is to certify that the above listed case reports have been verified by me from the records of this Hospital and these patients operated upon in this institution by Dr.——————; that the admission number and dates specified are correct. This is further to certify that the reports given the following sequence numbers (———— to ———— inclusive) were from the residency service of the aforementioned physician and the reports given the following sequence numbers (——— to ——— inclusive) were from his own practice (ward or private) in this Hospital and that in all instances he was the chief operator.

.... Signature

.... Official Title

Date..................................

Each case report should be typewritten on standard size paper, 8½ x 11 inches, and those reports then assembled in sequence. Covers should not be used for separate reports, as this increases their bulk unduly. Reports should be bound loosely together in a light outside cover not larger than 10 x 12 inches, so that they may be opened and held like a book. The following items should be observed:

I. Each case report should be headed by identifying information corresponding with that of the index lists, including sequence number, designation as a "Residency" or "Own Practice" case, and so on.

II. The report of the case should begin with:

1. Preoperative diagnosis.
2. Postoperative diagnosis (based on findings).

III. The report should be in condensed form, not reported in detail. Follow-up findings of not less than six (6) months are essential. Omissions of follow-up examinations must be explained and justified.

IV. Obstetrical reports which do not include essential pelvic measurements and note of methods used, will be considered incomplete.

V. Critical summary or analysis of each report with critical deductions derived from correctness or incorrectness of candidate's procedures and from final results must be a final part of each report. Lacking such summary, *reports will be considered incomplete and will not be graded.*

GRADUATE TRAINING RESIDENCIES

This board, through the Council on Medical Education and Hospitals of the American Medical Association, has approved institutions providing acceptable residencies in obstetrics and gynecology.

The American Board of Obstetrics and Gynecology has established the following requirements for its approval of a residency in a hospital department or service:

1. It is most desirable that the Chief of Service of the Department be certified by the board, in the interests of the proper teaching of the specialty of obstetrics and gynecology. In lieu of such certification the board will approve of individuals of recognized high professional standing in the specialty. At least one additional senior member of the staff should be similarly qualified.

2. Exceptions to the foregoing, in respect to the certified status of Chiefs of Service and others as outlined above, can be made by assent of the Committee on Residency Training for adequate and justifiable reasons. As examples of the latter, the degree of F.A.C.S. in obstetrics-gynecology may be accepted in lieu of one of the two required certifications if the general reputation of the person concerned is known to the Committee as national or sectional in scope, or a professorial rank without certification might be acceptable.

3. In instances where the services of obstetrics-gynecology not combined but are separate in any given hospital, the Chief of each such service seeking approval and at least one of his subordinates must be certified or otherwise qualified as outlined above.

If obstetrics and gynecology are not combined in one department, approval can be granted only if arrangements are made for some degree of rotation of residents between both services, provided both services are separately approved.

4. If gynecology is classified in the given hospital as a subdivision or subservice of general surgery, approval cannot be granted for residency training in gynecology. Exceptions have been made if the subdivision of gynecology is headed and staffed by a chief and at least one other certified by this board or otherwise qualified as specialists in obstetrics-gynecology, as specified above, thus insuring an acceptable educational program in obstetrics-gynecology.

5. Effective July 1, 1948, "temporary approvals pending survey" were discontinued. It is expected that all presently approved hospitals will soon be initially surveyed, if holding temporary approval, or resurveyed and redesignated if holding unconditional approval.

6. Departments holding official approvals for residency training are cautioned that their totals of residents appointed must be kept to the number specified in the A. M. A.—American Board approval notification. Dilution of training facilities by unauthorized appointment of residents in excess of these numbers may be cause for reinspection and changes in approval status of such hospitals and their special services.

7. For further details of requirements and qualifications for approval for residency training, hospital officials should refer to the latest special issues of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION as they appear during each year, dealing with these subjects, *or should apply to the Council on Medical Education and Hospitals of the American Medical Association for bulletins entitled Essentials of Approved Residencies and Fellowships.*

8. Application for residency approval must be made in triplicate on special forms provided for this purpose. These forms may be obtained from the Secretary of the Council on Medical Education and Hospitals of the American Medical Association. All statements amplifying an application should also be made in triplicate. The hospital should keep a duplicate of all papers.

9. The formal application, with all papers, for residency training approval should be submitted primarily to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois. Action is taken jointly by the Council and this Board after survey by the Council.

10. Approvals are granted according to adequacy of the training program and teaching facilities of various institutions on the following several bases: (a) one-year approval in obstetrics and gynecology (combined) or one-year approval in obstetrics and/or in gynecology (separate), correlated basic science instruction being an essential part of the first year; (b) two-year approval in obstetrics and gynecology (combined) or two-year approval in obstetrics and/or in gynecology (separate), provided there is opportunity in the latter instances for some degree of rotation between the two services as well as laboratory instruction in basic sciences; (c) three-year approval in obstetrics and gynecology (combined) or in obstetrics or in gynecology, provided there is opportunity for one to one and one-half years' service in the branch of the specialty opposite to that in which the candidate holds appointment, as well as laboratory instruction in the basic sciences of both branches.

Three (3) years' approval is available to institutions holding active medical school teaching affiliations. Other institutions may acquire three (3) years' approval if their educational programs and teaching facilities are adequate for such approval. Probably the most desirable type of approval, from the hospital's standpoint, is that of two (2) years in obstetrics and gynecology, because of the greater flexibility regarding appointments. These two (2) years may be the first two (2) following a trainee's internship or they may be the last two (2) of his formal training following an internship plus one (1) year of acceptable training in the specialty. A service with two-year approval may also, if it desires, appoint a man for only one (1) year, as for example, if he has already had two (2) years of approved training.

Many institutions with three-year approval appoint a group of men for the first year, promoting only part and releasing some of them at the end of this time. Other institutions are accredited for only one (1) year and both will from year to year provide partly trained men for the two-year institutions, which may thus complete a candidate's required training.

Some institutions may be granted one-year approval either because of limited facilities or, in certain instances, because of the preference of the institution which may require that candidates for such positions must show evidence of having completed two (2) years of satisfactory training.

No stipulation has been made that an institution holding only one-year training approval must provide this as the first year of a candidate's formal training. It may be his second or even his third year, responsibilities being graded accordingly, but if it is his first year laboratory basic science instruction is an essential part.

On the other hand, candidates may be promoted from year to year in one place for their entire service of three (3) years if this institution is so approved and listed.

Exchange residencies within the specialty between approved institutions are acceptable and to be encouraged. Many authorities believe that training in more than one institution is broadening to the candidate. "Farming out" to unapproved institutions or services is not acceptable unless the work of such services is directly and carefully supervised by the Chiefs of the service in the approved hospital under which the man is actively appointed and working. This should be attested by such Chiefs.

Exchange residencies into other specialties cannot be permitted to subtract from the minimal required three (3) years of training divided between obstetrics-gynecology.

As noted elsewhere, two (2) years of post-training practice limited to the specialty is necessary before a candidate becomes eligible for certification.

This board has no objection to residency services being arranged by hospitals for periods longer than three (3) years, unless this dilutes the candidate's clinical training opportunities too much during the first three (3) years. However, the board does not accept a fourth year, or more, of residency training as a substitute for any part of the required two (2) years of post-training practice. The importance of post-training practice in the specialty is emphasized as an opportunity for maturing of the candidate and for colleague appraisal of a man's ability when working on his own responsibility in his chosen community.

Exception to this ruling may be made for men advancing from their training into and planning to remain in full-time teaching positions. These men then must complete at least two (2) years in such positions. Consequently the only institutions in which men may work as fourth and fifth-year residents and obtain credit for this time as "post-training practice" are those directly affiliated with approved schools of medicine as teaching hospitals for undergraduate instruction. These "full-time" men must hold faculty appointments, must have teaching duties with undergraduate students, must be given independent authority more than that of residents, and must make a declaration of intention to remain in full-time teaching work.

11. Lists of officially approved institutions for formal residency training appear regularly in certain issues of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Detailed information about any of these can be obtained from the Association.

12. Any physician formally obligating himself to serve a residency in a Council on Medical Education and Hospitals of the American Medical Association-American Board of Obstetrics and Gynecology approved hospital and thereby eliminating other possible candidates from the position, who breaks his contract without justifiable cause, either before beginning his service or during his period of service, except by mutual consent and agreement between the candidate and the hospital, may be barred from the examinations for certification at the discretion of the board.

13. It should be recalled by all concerned that credits for graduate training may be obtainable in certain instances for residency or assistantship service in hospitals not officially approved for residency training. Each such case must be individually considered, and credits will be largely dependent on the teaching qualifications of those in charge of the service, and the clinical facilities of the hospital in question.

PRECEPTORSHIP TRAINING

After July 1, 1955, the board will no longer accept training solely by preceptorship in fulfillment of educational requirements for admission to examination. To be eligible for preceptorship thereafter the candidate must have had a minimum of one year formal residency training in an institution approved by the Board for Residency Training in obstetrics and/or gynecology.

After the above date candidates who apply for preceptorship training must notify the secretary of the board of such intent and give the name of the proposed preceptor. He must also request the preceptor immediately to notify the secretary of the board in writing, giving hospital connections, available clinical material, opportunity for basic study, and the plan of the proposed teaching program. As has long been true of residency training programs such as preceptorship, arrangements will be reviewed by the residency training committee of the board in advance for approval or disapproval. If the program is approved, the official preceptorship training form will be forwarded to the preceptor.

The preceptor must supervise closely the candidate's work and keep an informative record of the candidate's performance. The preceptor and the preceptee shall report in writing to the Secretary of the Board at the end of each six months of preceptorship, outlining the progress of the training program. This information will be placed in the candidate's application for admission to examination in order that it may be evaluated by the credentials committee.

As a general rule each year of preceptor training will receive a six months' credit toward the total of three years of training necessary for admission to examination. As is the case with candidates whose training has been entirely by formal residency, each application will be evaluated finally by the credentials committee.

An acceptable preceptor preferably shall be one certified by the American Board of Obstetrics and Gynecology and must have been certified for a minimum of five years. Fellowship in the American College of Surgeons or long experience and established reputation as an obstetrician-gynecologist without either of the above qualifications may qualify the preceptor.

Preceptor and preceptee must work in a hospital approved by the Joint Commission on Accreditation of Hospitals.

The pretraining practice requirements cannot be carried on concurrently with preceptorship training.

CERTIFICATION

Each certificate granted or issued does not itself confer or purport to confer on any person any degree or legal qualifications, privileges or license to practice obstetrics or gynecology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to standardize qualification for specialists in obstetrics and gynecology, and to certify as specialists those who voluntarily appear before the board for such recognition and certification, according to its regulations and requirements.

The board does not subscribe to any hospital rule that certification is to be required for medical appointments especially in ranks lower than chief or senior staff of hospitals, or associate professorship in schools of medicine, for the obvious reason that such appointments constitute desirable specialist training.

Even though certification or its full equivalent may be considered a desirable requisite to appointment in key positions, as on the senior or chief staff, particularly of hospitals expecting to conduct approved services for training of residents, it was never intended by this board that certification should be required by any hospital as a prerequisite to appointment, especially in such lesser positions.

AMERICAN BOARD OF OPHTHALMOLOGY

Derrick T. Vail, Chairman, Chicago.
Walter S. Atkinson, Vice Chairman, Watertown, N. Y.
William L. Benedict, Consultant, Rochester, Minn.
Conrad Berens, Consultant, New York.
Frederick C. Cordes, Consultant, San Francisco.
Walter B. Lancaster, Consultant, Boston.
Georgiana D. Theobold, Consultant, Oak Park, Ill.
Francis H. Adler, Philadelphia.
James H. Allen, New Orleans.
Alson E. Braley, Iowa City, Iowa.
Gordon M. Bruce, New York.
Paul A. Chandler, Boston.
John H. Dunnington, New York.
F. Bruce Fralick, Ann Arbor.
Michael J. Hogan, San Francisco.
Brittain F. Payne, New York.
Edwin B. Dunphy, Secretary-Treasurer, Boston.
Merrill J. King, Assistant Secretary.
Miss Lea M. Stelzer, Registrar, 56 Ivie Road, Cape Cottage, Maine.

Address all communications to the American Board of Ophthalmology, Cape Cottage, Maine.

NO DEGREES OR LEGAL RESTRICTIONS

Each certificate granted or issued does not of itself confer or purport to confer on any person any degree or legal qualifications, privileges or license to practice ophthalmology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to elevate the standards of qualification for specialists in ophthalmology and to certify as specialists doctors of medicine who appear before the board for such recognition and certification, according to its requirements and regulations.

REQUIREMENTS

All candidates must comply with current board regulations regardless of time of filing application.

The secretary is not permitted to make decisions as to requirements. These rulings are made only by the Committee on Credentials after reviewing the candidate's formal application.

PREREQUISITES

1. High ethical and professional standing.
2. Full citizenship in the country where the candidate practices. (Limited to countries of North and South America, their possessions and territories and the Philippine Republic.)
3. A degree from a medical school of high standing, satisfactory to the board and approved by the Council on Medical Education and Hospitals of the American Medical Association. An applicant whose training has been received outside of the United States and Canada must present credentials satisfactory to the board and is required to have the certificate of the National Board of Medical Examiners if he has been in practice less than ten years.
4. Completion of an internship of not less than one year in a hospital approved by the same Council.
5. Completion, by the time of the written Qualifying Test, of not less than thirty-six months (a total of sixty months is required of candidates practicing both ophthalmology and otolaryngology) of combined study, training and practice of ophthalmology in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships and private practice.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application forms must be filled out completely and accurately. Letters of endorsement, together with any other required credentials, must be sent to the secretary's office before the deadline date.
2. Fee of $100 remitted with application.
3. A list of papers or books published.
4. Written qualifying test.
5. Practical examination.
6. Special review of ophthalmic surgery.
7. Membership in the American Medical Association, or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association.

FEES

For written test and original examination, $100 (as mentioned above).

Repeating Written Qualifying Test, $65.

Repeating Practical Examination, $65.

Single conditions, Written or Practical, $25.

Two or more conditions, $35.

Written qualifying test must be taken within three years of date of application. Thereafter new application and fee are required.

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

SPECIAL TRAINING

This shall include:

1. Graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology, pharmacology, disorders of ocular motility and binocular vision, perimetry, and in the skilful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp and microscope. Mere factual knowledge is not sufficient; the candidate must have had training in the application of these subjects and in their use in clinical ophthalmology, especially in refraction.
2. Active clinical experience in approved hospitals, clinics, dispensaries and private practice. Library and laboratory facilities should be utilized for intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the board.

These requirements may be met in various ways:

BASIC STUDIES

Anatomy
Embryology and developmental abnormalities
Biochemistry
Pathology
Bacteriology and immunology
Optics and physiologic optics
Ocular physiology
Medical Ophthalmology
Therapeutics and pharmacology
Neuro-ophthalmology

These may be covered by:

A. *Graduate Study.*—By a curricular course in the basic sciences related to ophthalmology in an approved graduate medical school.

B. *Postgraduate Study.*—By courses in individual basic sciences related to ophthalmology as given at various approved institutions. The Home Study Course of the American Academy of Ophthalmology and Otolaryngology is recommended.

C. *Residency.*—By advanced study of these subjects during a residency and by correlation of the principles involved with clinical problems.

D. *Research, Fundamental and Clinical.*—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic sciences into direct relation with the concrete clinical problem.

CLINICAL EXPERIENCE

A. By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the entire field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff and the method of presentation as well as the subject matter critically considered.

B. By residencies in hospitals where regular instruction by lectures and quizzes and seminars is not available. The syllabus issued by the board will guide the resident in his selection of topics to be studied.

C. By fellowships in ophthalmology.

D. By preceptorship with a well trained and critical ophthalmologist.

E. After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F. Research under competent critical and sympathetic supervision will give first hand insight into (1) the methods whereby old knowledge was and new knowledge is acquired and (2) the pitfalls which accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate basic facts in the intelligent critical way which is expected of the specialist in practice.

G. The candidate who cannot secure the type of residency he desires should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

WRITTEN QUALIFYING TEST

Before being accepted for examination, candidates are given a written test to ascertain their qualifications. The questions may cover any part of ophthalmology and are especially devoted to the basic studies as listed above. The written test will be given in several principal cities at the same time. Choice of cities is determined largely by the geographical distribution of candidates. Candidates found acceptable will be notified to appear for a subsequent practical and clinical examination in ophthalmology.

EXAMINATIONS

Examinations usually are held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the board, depending on the number of applications from any region.

The board reserves the right to limit the number of candidates to be admitted to any one examination.

Candidates must be examined in all subjects listed in the sections titled Basic Studies and Practical and Clinical Examination. The time spent in preparation will count less than the knowledge and experience acquired as shown on examination.

PRACTICAL AND CLINICAL EXAMINATION

The subjects of the practical examination are as follows: (1) External Diseases, (2) Ophthalmoscopy, (3) Histopathology, (4) Refraction, (5) Motility, (6) Ophthalmic Surgery, and (7) Perimetry.

1. *External Diseases of the Eye and Adnexa.*—Various methods of examination, diagnoses and treatment.

2. *Ophthalmoscopy.*—Patients will be examined by the candidate and the findings described or drawn. A candidate is required to bring his own ophthalmoscope.

3. *Pathology.*—The candidate will demonstrate familiarity with general clinical pathology as well as the etiology, pathology and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize normal and pathologic histology of the eye.

4. *Refraction.*—A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. *Motility.*—The candidate will demonstrate on patients his familiarity with routine methods of examination and diagnosis.

6. *Ophthalmic Surgery.*—Examination of surgical patients and discussion on principles of ophthalmic surgery.

7. *Perimetry.*—The candidate will be given an opportunity to examine patients by use of the arc perimeter, the tangent screen and the stereocampimeter. He may also be required to interpret charted fields.

SPECIAL REVIEW OF SURGICAL CASES

The board now requires of all candidates a list of ophthalmic operations performed within two years prior to examination. This list is to be presented with application.

The operations should be listed in groups of each type of surgery. The numbers of operations in each group must be totalled and the total number of all operations shown. This list must contain the following data:

1. Date.

2. Condition or conditions for which operation was performed. Complications during hospitalization.

3. Name and character of operation.

4. Identification by hospital or clinic number, or the name of a consultant or conferee who was present at the time of operation.

Circumstances which prevent any candidate from fulfilling this requirement should be fully explained, with detailed statement of candidate's surgical experience.

CERTIFICATION

The decision of the board is final as to the candidate's passing, failure or partial failure. The final action of the board is based on the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examinations.

REEXAMINATION

Candidates may be reexamined as often as they desire on satisfactory evidence of adequate additional preparation and payment of reexamination fee. A minimum of one year must elapse between examinations when a candidate is conditioned in one or more subjects. A minimum of two years additional preparation is required of candidates who fail in all subjects. The board may, at its discretion, deny the candidate the privilege of reexamination.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY

Clarence H. Heyman, President, Cleveland.
William T. Green, Vice President, Boston.
Hugh Smith, Memphis.
Don E. King, San Francisco.
William M. Roberts, Gastonia, N. C.
Mather Cleveland, New York.
Charles J. Frankel, Charlottesville, Va.
George J. Garceau, Indianapolis.
Harold A. Sofield, Secretary-Treasurer, 122 S. Michigan Ave., Chicago 3.

RULES AND PROCEDURES

1. General Eligibility Requirements

1. Satisfactory moral and ethical standing in the profession.

2. Graduation from a medical school of the United States or Canada, recognized at the time of graduation by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered satisfactory by the aforementioned Council.

3. Completion of an internship of not less than one year in a hospital approved at that time by the Council on Medical Education and Hospitals of the American Medical Association or, if trained in foreign countries, in institutions considered satisfactory by the American Board of Orthopaedic Surgery.

4. Starting in 1952 and continuing subsequently, applicants taking Part I examinations for the first time must have completed not less than one year of resident training in general surgery in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, or present evidence of comparable training in general surgery considered satisfactory by the American Board of Orthopaedic Surgery. The minimum of one year of training in general surgery is in addition to the minimum of one year of internship.

5. Completion of formal requirements for Part I or Part II examinations. These formal requirements can be satisfied only by training in one or two categories:

(*a*) resident orthopedic training
(*b*) preceptorship training

Applicants may no longer be admitted to examinations, or be certified, on the basis of extensive specialized practice and/or teaching appointments and/or many short unapproved courses.

6. Restriction of practice to orthopedic surgery.

II. REQUIREMENTS FOR PART I EXAMINATIONS

1. Completion of and compliance with aforementioned general eligibility requirements.

2. Citizenship in the United States or Canada, or possession of citizenship papers showing intent to become a full citizen.

3. Satisfactory completion of a minimum of one year of approved training in orthopedic surgery under a program of resident orthopedic training, or completion of a minimum of five years of orthopedic training under a preceptorship program.

Starting in 1952 and continuing subsequently, in addition to the aforementioned requirements, applicants taking Part I examinations for the first time will be required to have satisfactorily completed a minimum of two years of approved training in orthopedic surgery instead of one year previously required. Applicants training on preceptorship programs will still be required to have completed a minimum of five years of orthopedic training.

4. Evidence of competence in training.

5. Approval for examination by the Committee on Eligibility of The American Board of Orthopaedic Surgery.

III. REQUIREMENTS FOR PART II EXAMINATIONS

1. Successful completion of Part I examinations.

2. Full citizenship in the United States or Canada.

3. License to practice in the United States or Canada.

4. Membership in the American or Canadian Medical Association.

5. Satisfactory completion of a minimum of three years of approved resident training in orthopedic surgery, plus a minimum of two subsequent years of practice period for applicants trained under resident orthopedic training programs.

6. Satisfactory completion of a minimum of five years of practice period for applicants trained under preceptorship programs.

7. Evidence of competence in practice.

8. Approval for examination by the Committee on Eligibility of the American Board of Orthopaedic Surgery.

IV. APPLICATION AND EXAMINATION FEE SCHEDULE

1. Application for Part I, fee $15, not returnable.

2. Examination, Part I, fee $35, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

3. Application for Part II, fee $15, not returnable.

4. Examination, Part II, fee $50, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

5. Reexamination, Part I, fee $35; for Part II, fee $50. No application fee is required for reexamination.

V. APPLICATIONS

1. Applications for Part I examinations must be received in the office of the secretary of the board before November 30 of the year preceding the examinations.

2. Applications for Part II examinations must be received in the office of the secretary of the board before August 15 of the year preceding the examinations.

3. Notices of acceptance for admission to the Part I examinations are mailed to eligible candidates during the month of February in the year of the examinations.

4. Notices of acceptance for admission to Part II examinations are mailed to eligible candidates during the month of November in the year preceding the examinations.

5. Questions of eligibility for examinations are decided by the Committee on Eligibility of the board. This committee meets twice yearly. The secretary is not empowered to rule on questions of eligibility.

VI. EXAMINATIONS

1. Part I examinations are held once yearly, usually in April or May, in various centers in the United States.

2. Part II examinations are held once yearly, usually in one center, immediately preceding the meeting of The American Academy of Orthopaedic Surgeons.

VII. CERTIFICATION

1. Applicants who successfully pass Part I examinations will receive no certificate but will be notified by letter by the secretary.

2. Applicants who successfully pass Part II examinations receive a Certificate of the Board which states that they have been found qualified to practice the specialty of orthopedic surgery in those fields in which they have been trained and examined.

3. Candidates obtaining certification without training and examination in children's orthopedic surgery may subsequently add certification in children's orthopedic surgery by completing a minimum of one year of approved resident orthopedic training in children's orthopedic surgery and successfully passing examination in that field. A practice period of one year is required following completion of resident training, prior to examination for additional certification.

VIII. APPROVED RESIDENCIES

1. In the United States, resident training must be taken in institutions approved for resident training in orthopedic surgery by the Council on Medical Education and Hospitals of the American Medical Association. All approved institutions are listed at frequent intervals in the Internship and Residency number of THE JOURNAL. Lists may be obtained from the American Medical Association and are not obtainable from the board.

2. The integral parts of approved residencies are designated in lists by the following symbols: A—Adult Orthopedic Surgery; C—Children's Orthopedic Surgery; F—Fracture Surgery; and S—Basic Science training. Approved lengths of training in institutions is also designated.

3. Candidates electing an additional year of training in adult orthopedic surgery and fracture surgery in lieu of a year in children's orthopedic surgery may satisfy requirements by continuing their training beyond the designated approved length of time in institutions approved for adult orthopedic surgery or adult orthopedic surgery and fractures.

4. Credit for resident training is not retroactive. Candidates must receive resident training in institutions during periods that such institutions are on the approved list. If candidates are in training at institutions at the time that such institutions become approved, resident training credit may be granted from the start of the training period provided that the program is judged to have been satisfactory.

5. Candidates in resident training, or possessing signed contracts for future resident training in institutions which become disapproved, either in whole or part, receive resident training credit for the entire period during which their contracts are in force.

6. The term "fellow" is considered synonymous with "resident" when the position occupied and the work performed is equal in all functions. Fellowships in institutions having residents, in which training and responsibilities are not equal, are not credited as resident training.

7. Institutions approved for resident training in orthopedic surgery by the Council on Medical Education and Hospitals of the American Medical Association may, with prior acceptance by the American Board of Orthopaedic Surgery and notification

to the Council, utilize the training facilities of institutions not individually approved for resident training by the aforementioned Council, provided that:

(*a*) The training supplements services in the same categories in which the institution responsible for training is approved by the Council.

(*b*) The resident spends at least half of the minimum required time in each category of training in institutions approved by the Council.

8. Foreign residencies must satisfy the American Board of Orthopaedic Surgery.

9. Application for approval of the training facilities of any institution must be made to the Council on Medical Education and Hospitals of the American Medical Association, and inspection of such facilities is made by representatives of the Council. Final approval is a joint function of the Council and the American Board of Orthopaedic Surgery.

IX. REQUIREMENT OF RESIDENT ORTHOPEDIC TRAINING

1. Institutions approved for full three year programs including all parts of the training requirements may integrate all parts so that they are given concurrently.

2. Institutions now approved for less than three years of orthopedic resident training should arrange with other approved institutions to provide complete three year programs for all residents. It is planned that such desirable complete programs, with their participating institutions, will be listed separately.

3. The minimum requirements of resident orthopedic training are as follows:

(*a*) One year of training in adult orthopedic surgery.

(*b*) Six months of training in the basic sciences.

(*c*) Six months of training in fracture surgery.

(*d*) One year of training in children's orthopedic surgery or, if elected, an additional year of training in adult orthopedic surgery and fracture training in place of training in children's orthopedic surgery.

4. Candidates who elect an additional year of training in adult orthopedic and fracture surgery instead of a year in children's orthopedic surgery may satisfy the requirements by taking the additional year of training in adult orthopedic surgery or six months of adult orthopedic surgery and six months of fracture surgery, but may not take the entire year of training in fracture surgery.

5. Training in adult and children's orthopedic surgery must include observation and first hand experience in diagnosis, treatment, operative and postoperative care of orthopedic problems.

6. Training in fracture surgery must include observation and first hand experience in diagnosis, treatment, operative and postoperative care of recent and old fractures.

7. Training in the basic sciences must instill a sound knowledge of anatomy, pathology, physiology, bacteriology and biochemistry as these basic sciences apply to orthopedic surgery.

8. Candidates may complete the training requirements by training in several approved institutions provided that all the aforementioned minimum requirements are satisfied on approved services.

9. No training period of less than six consecutive months in one institution may be credited toward resident training requirements, except a few short courses on the board's approved list and recognized supplementary services of approved institutions.

10. Candidates in resident training may not engage in private practice.

11. Candidates in resident orthopedic training must receive their training in institutions and may not receive credit for time spent assisting in private office practice, which is considered as preceptorship training.

12. Candidates trained on accelerated programs during the war years are credited with one year of training for each nine months' residency on established accelerated programs.

X. REQUIREMENTS OF PRECEPTORSHIP TRAINING

1. The preceptor must possess certification by the American Board of Orthopaedic Surgery.

2. The practice of the preceptor must be extensive enough to give the candidate experience in all phases of orthopedic practice.

3. The preceptor must devote special periods of time each week, outside of the routine hours employed in hospitals and office practice, to assist the candidate with organized courses of study similar to those received during resident training.

4. If facilities and instruction in the related basic sciences are not available, the candidate must spend a minimum of six months as a student in an institution approved for basic science training in orthopedic surgery.

5. The candidate must train as a full time assistant to the preceptor and may not maintain a separate office or engage in individual practice.

6. The minimum training period in orthopedic surgery under the preceptorship program is five years, after which time the candidate may file application for Part I examinations.

7. The minimum practice period required for candidates trained under the preceptorship program is five years, after which time the candidate may file application for Part II examinations. This makes a minimum total of 10 years from the start of orthopedic training to eligibility for Part II examinations.

8. The practice period may be satisfied in individual private practice or in assistantship or partnership as desired by the candidate.

9. Candidates who combine preceptorship training with approved resident training receive credit for the preceptorship portion of their training only if it totals a minimum of two years. Two years of preceptorship training are credited as the equivalent of one year of resident training. The practice period requirement is likewise evaluated so that three years of practice are required if the candidate submits two years of preceptorship and two years of resident training, and four years of practice are required if four years of preceptorship and one year of resident training are submitted.

XI. SEQUENCE OF EXAMINATIONS AND PRACTICE REQUIREMENTS

1. No person may take Part II examinations until after successful completion of Part I examinations.

2. Successful completion of Part I examinations in no way obligates the board to declare a candidate eligible for Part II examinations.

3. Regardless of how extensive or prolonged a practice a candidate may have had prior to completing the training requirements, such time may not be credited toward practice requirements. All practice requirements must be satisfied subsequent to completion of training requirements.

4. Candidates may not be admitted to examinations on the basis of prolonged practice but must qualify on the basis of formal training in one of the categories previously detailed.

XII. PRACTICE REQUIREMENTS

1. Candidates must maintain high ethical and professional standards.

2. Candidates must strive to increase their scientific knowledge.

3. Candidates must limit their practice to orthopedic surgery.

4. Candidates who have had no approved training in children's orthopedic surgery must confine their practice to fracture and adult orthopedic surgery.

5. Candidates trained in resident orthopedic training are required to complete a minimum of two years of orthopedic practice subsequent to the completion of their formal training before becoming eligible for Part II examinations.

6. Candidates in private or institutional practice must spend a minimum of 14 months in one locality immediately prior to application in order that practice may be properly evaluated.

7. Candidates employed full time in institutions may satisfy practice requirements by serving a minimum of two years, but minimum requirements may not be satisfied by mixing full-time institutional work with preceding or subsequent time in private practice.

8. Candidates trained by preceptorship are required to complete a minimum of five years of orthopedic practice before becoming eligible for Part II examinations. The practice period may be independent of the preceptor.

XIII. Method of Examination

1. Part I examinations consist of a written examination and oral examinations. Material covered includes fundamental surgical principles, elementary fracture and orthopedic procedures, history-taking and physical examinations as well as those parts of anatomy, pathology, physiology and biochemistry related to orthopedic surgery. The oral examinations consist of five parts: (*a*) anatomy, (*b*) pathology, (*c*) physiology and biochemistry, (*d*) surgery and (*e*) fractures and orthopedic surgery.

2. Part II examinations consist of a written examination and oral examinations. Material covered includes advanced work in all phases of orthopedic surgery. The oral examinations consist of five parts: (*a*) anatomy, (*b*) pathology, (*c*) children's orthopedic surgery, (*d*) fractures and (*e*) adult orthopedic surgery.

3. Candidates who have not had approved training in children's orthopedic surgery will not be examined in that branch of orthopedic surgery.

4. Candidates are notified by letter as to whether they passed or failed in the examinations. No information regarding results is available until such letters are mailed.

5. Results of integral parts of examinations are not available to either candidates or diplomates of the board.

6. Candidates who have passed Part I examinations are required to take Part II examinations within a 10 year subsequent period. If there is a lapse of more than 10 years, candidates must repeat Part I examinations and must then become eligible by the requirements then in force.

XIV. Reexaminations

1. Applicants who fail to pass Part I or Part II examinations may be reexamined a second or third time in each Part, but must pay the prescribed examination fee each time of reexamination.

2. Applicants who fail to appear for second and, if necessary, third reexaminations within three years after first failure must submit new applications with the appropriate fees.

3. After three successive failures in Part I or Part II examinations, applicants must present evidence of additional orthopedic training satisfactory to the board before submitting new applications.

XV. Military Service

1. Medical officers who have elected service in the military forces as their life careers compete for certification on the same basis as do doctors in civilian practice.

2. Doctors who served for a minimum of one year in the military forces during the war years, between Jan. 1, 1941, and July 1, 1946, are granted a bonus of one year of practice credit, provided that the same time is not used for resident training credit.

3. Applicants who served in military hospitals whose service is judged by the board to have been equal to that of approved resident orthopedic training, and who were on such service for a minimum of one year between Jan. 1, 1941, and July 1, 1946, may be granted credit for one year of resident orthopedic training, provided that the same time is not used for practice credit. Applicants requesting such credit must submit completed "Record of Professional Assignments" booklets with their applications.

4. No applicant may be granted more than one year of resident training credit and one year of practice credit for military service during the war years.

5. After July 1, 1946, credit for orthopedic training must have been or must be obtained by assignment as residents in military hospitals on the approved list for resident orthopedic training, the same as in civilian life.

6. Medical officers assigned to civilian institutions on the approved list for resident orthopedic training receive the same credit as do civilian candidates.

7. Medical officers who have elected service in the military forces as their life careers must satisfy the practice requirements by military assignments in which their duties are limited to the practice of orthopedic surgery.

XVI. Records of Surgical Cases and Inspections

1. Records of a specified number of consecutive surgical cases may be requested by the board in order to evaluate properly the work of an applicant.

2. A representative of the board may visit a community in order to evaluate properly the work of an applicant.

AMERICAN BOARD OF OTOLARYNGOLOGY

Officers of the Board

Frederick T. Hill, President, Waterville, Maine.
Gordon D. Hoople, Vice President, Syracuse, N. Y.
Dean M. Lierle, Secretary-Treasurer, University Hospitals, Iowa City.

Senior Counselors

George M. Coates, Philadelphia.
Ralph A. Fenton, Portland, Ore.
Gordon F. Harkness, Davenport, Iowa.
Carl H. McCaskey, Indianapolis.
Harris P. Mosher, Marblehead, Mass.
W. E. Sauer, St. Louis.
Ernest M. Seydell, Wichita, Kan.
Frank R. Spencer, Boulder, Colo.
Fletcher D. Woodward, Charlottesville, Va.

Board of Directors

Lawrence R. Boies, Minneapolis.
Louis H. Clerf, Philadelphia.
Russell M. Decker, Pasadena, Calif.
Lyman H. Heine, Fremont, Neb.
Frederick T. Hill, Waterville, Maine.
Gordon D. Hoople, Syracuse, N. Y.
Percy E. Ireland, Toronto, Canada.
Francis E. Le Jeune, New Orleans.
Dean M. Lierle, Iowa City.
H. I. Lillie, Rochester, Minn.
John R. Lindsay, Chicago.
Bernard J. McMahon, St. Louis.
William J. McNally, Montreal, Canada.
James H. Maxwell, Ann Arbor, Mich.
Philip E. Meltzer, Boston.
Lewis F. Morrison, San Francisco.
Werner Mueller, Boston.
C. Stewart Nash, Rochester, N. Y.
Henry B. Orton, Newark, N. J.
Arthur W. Proetz, St. Louis.
LeRoy A. Schall, Boston.
Harry P. Schenk, Philadelphia.
O. E. Van Alyea, Chicago.

Assistants

Daniel S. Cunning, New York.
Francis L. Lederer, Chicago.

GENERAL REQUIREMENTS

The following general qualifications of candidates for examination are required by the board:

1. A candidate must have been a citizen of the United States or the Dominion of Canada for three years or more.

(*a*) A candidate must have been a graduate five years or more of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(*b*) A candidate must be of known good moral character and be ethical in his professional relationships.

(*c*) A candidate trained in a foreign country must be able to give proof of medical and graduate training comparable to the requirements of the Board.

(*d*) A candidate from the United States or the Dominion of Canada must be a member of the American Medical Association or of the Canadian Medical Association respectively or other such medical societies of equal standing as are recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Candidates from foreign countries, who have received their training in otolaryngology in the United States are eligible for examination at the discretion of the board, providing they show proof that they are permanent residents and citizens of their respective foreign countries and provided they meet the general academic requirements of the board.

SPECIAL REQUIREMENTS

1. A candidate must have had a general internship, of at least one year, in a hospital approved by the Council on Medical Educations and Hospitals of the American Medical Association.

2. A candidate must be proficient in the applied basic sciences, fundamental to the intelligent practice of otolaryngology. These include anatomy of the ear, nose and throat, neck, chest, esophagus and nervous system, gross pathology and histopathology, bacteriology, physiology, didactic otolaryngology and the general fundamentals of surgery. (This requirement may be fulfilled in a residency or fellowship service or in an approved organized postgraduate course.)

3. In addition to the general internship, the required clinical training in otolaryngology may have been acquired in any of the following ways:

(*a*) A three years' approved residency or fellowship in otolaryngology approved by the Council on Medical Education and Hospitals of the American Medical Association.

(*b*) A four years' approved residency or fellowship in otolaryngology and ophthalmology approved by the Council on Medical Education and Hospitals of the American Medical Association, provided one half of the training has been in otolaryngology.

(*c*) A two years' approved residency or fellowship in otolaryngology or a three years' approved combined residency or fellowship in otolaryngology and ophthalmology, provided two years have been in otolaryngology and have been preceded by at least one year's residency training in surgery or medicine, or by an additional year in an approved internship.*

4. In exceptional circumstances certain candidates who cannot meet all of the above requirements may be accepted for examination, on recommendation of the Credentials Committee, substantiated by action of the board.

5. At least one year must be spent in private, group or institutional practice of otolaryngology following the period of special training. This requirement may be waived in cases of candidates of foreign countries who are permanent residents and citizens of their respective countries and who are returning there for the practice of otolaryngology.

6. A candidate may be qualified for examination, at the discretion of the American Board of Otolaryngology, if in addition to the General Requirements and Special Requirements, no. 1 and 2, he has limited his practice to otolaryngology for seven years in association with a hospital staff approved by the Council on Medical Education and Hospitals of the American Medical Association.

7. A limited certificate in one of the subspecialties of otolaryngology may be issued, at the discretion of the board, to an exceptionally well qualified individual, *in the special field in* which the certificate is desired.

All candidates must comply with current board regulations, regardless of the time of filing application.

APPLICATION AND FEES

1. Application must be made in duplicate on special blanks procured from the secretary. The completed application blanks must be returned to the secretary, together with the other required credentials, at least 120 days in advance of the examination at which the candidate desires to appear.

2. The applications must be accompanied by two small photographs of the candidate, together with *verification* of the period of enrolment from the institutions where training in otolaryngology was obtained, and the names of two or more otolaryngologists, preferably diplomates of the board, from the vicinity of the candidate's place of residency, to be used as references.

3. The fee for the examination is $150. Of this sum $75 must accompany the application, of which $50 shall be returned if candidate is not accepted for examination. No application will be acted on until the $75 application fee is received. The remaining $75 of the total examination fee of $150 must be paid to the secretary on notification that the candidate has been accepted. A reexamination fee of $75 is required of candidates conditioned in one or more subjects.

4. The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expense.

5. The application remains valid for three years. An applicant must appear for examination within this time or forfeit the fee.

6. Candidates whose credentials have been found satisfactory and who meet the requirements of the board will be notified 90 days prior to the date of examination. The number of candidates who can be admitted to any one examination is limited. Due to a large number of applications on file, delay in assignment for examination may be inevitable. Appointments will be given in the order applications are accepted and on payment of the balance of the examination fee.

7. The board, acting as a committee of the whole, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final.

EXAMINATION

Examinations will be held at such time and place as the judgment of the board may dictate. Advance notice of examinations will be given in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and the several special journals devoted to otolaryngology. Insofar as is possible these will be held biannually at, or near, the time and place of meeting of the American Medical Association, or special societies, and of the American Academy of Ophthalmology and Otolaryngology. The examinations cover from two to four days.

Scope.—This examination encompasses all phases of otolaryngology and peroral endoscopy, including maxillofacial surgery, and surgery of the neck, excluding the thyroid.

The type of examination is as follows:

1. Clinical, covering the actual handling of patients, including history taking, physical and functional examinations, the use of laboratory and x-ray findings and a discussion of *differential* diagnosis.

2. Didactic, oral examinations covering all phases of otolaryngology.

3. Gross and microscopic pathology.

4. A written examination may be included when the board deems this advisable.

REEXAMINATION

A candidate who is conditioned in examination may be admitted to a subsequent examination after one year and within the three year period dating from his application, on payment of an additional fee of $75 and 120 days' notice of intention to appear is required.

---

* See Standards for Residencies in Otolaryngology published by the American Medical Association.

Candidates who have failed in the examination may be accepted for reexamination on recommendation of the Credentials Committee. *Satisfactory* evidence of further study and progress will be required. A new application must be filed. The fee for reexamination for such candidates is $150, $75 of which must accompany the application. The balance of the fee, $75, will be due on notification of acceptance.

CERTIFICATION

1. A certificate granted by the board does not of itself confer or purport to confer any degree or legal qualifications, privileges or license to practice otolaryngology, nor does the board intend or attempt in any way to interfere with or limit the professional rights and activities of any duly licensed physician. Its aim is to improve the standards of practice of otolaryngology and to certify as specialists those who voluntarily comply with its requirements and regulations.

2. The final action of the board is based on the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examinations.

AMERICAN BOARD OF PATHOLOGY

Robert A. Moore, President, St. Louis.
James B. McNaught, Vice President, Denver.
Roger Baker, Durham, N. C.
Israel Davidson, Chicago.
A. S. Giordano, South Bend, Ind.
James W. Kernohan, Rochester, Minn.
Douglas MacFayden, Chicago.
James N. Patterson, Tampa, Fla.
S. Brandt Rose, Philadelphia.
John R. Schenken, Omaha.
Edwin W. Schultz, Stanford, Calif.
Shields Warren, Boston.
William B. Wartman, Secretary-Treasurer, 303 E. Chicago Ave., Chicago 11.

A. General Requirements

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine or a certificate of the National Board of Medical Examiners.

3. Membership or associate membership in the American Medical Association or membership in a national society acceptable to the board by citizens of the United States. (At present, these include American Association of Pathologists and Bacteriologists, American Society of Clinical Pathologists, American Medical Association, or American Society for Experimental Pathology.) For citizens of other countries, membership in a national medical society of that country is required.

4. The applicant must devote his time primarily and principally to the practice of pathology.

B. Professional Education

1. Graduation from a medical school in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a medical school in other countries acceptable to the board.

C. Special Training and Experience

1. The board admits candidates to examinations who are otherwise eligible and who have had either of two following types of training and experience.

(*a*) After five years, if four of the five years have been in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board; or

(*b*) After eleven years if none of the training and experience has been in institutions so approved.

2. The specific requirements for those acceptable after five years are as follows:

(*a*) Pathologic anatomy only.

(1) Four years of supervised study and training in an institution approved for residency training in pathologic anatomy by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed twelve months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university for one of the four years. In addition, time, not to exceed twelve months, spent in a department of pathology of an approved school of medicine after the completion of the second year of undergraduate study may be counted for full credit toward the four years.

(2) One additional year which may be a continuation of the preceding or may be independent practice of pathologic anatomy in a hospital approved by the American Medical Association or other institutions acceptable to the board.

(*b*) Clinical pathology only.

(1) Four years of supervised study and training in an institution approved for residency training in clinical pathology by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed twelve months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university, for one of the four years. Candidates holding also a master's or doctorate degree in a special field of clinical pathology (bacteriology, serology, chemistry, parasitology or hematology) may obtain time credit for not more than twelve to twenty-four months toward the four years for this work, regardless of whether it was taken before or after the medical degree. The evaluation of time credit will depend on how much of the broad field of clinical pathology was covered in the graduate work.

(2) One additional year which may be a continuation of the preceding or may be independent practice of clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board.

(*c*) Pathologic anatomy and clinical pathology.

(1) Four years of supervised study and training divided as follows:

(*a*) Two years of supervised study and training in pathologic anatomy as outlined in the preceding paragraph 2-(*a*)-(1).

(*b*) Two years of supervised study and training in clinical pathology as outlined in the preceding paragraph 2-(*b*)-(1). Candidates declared eligible before July 1, 1953, may at their own election substitute one year (twelve months) of a straight or rotating clinical internship for one year of this special training in clinical pathology. After July 1, 1953, all candidates applying for both pathologic anatomy and clinical pathology will be required to have two years of supervised training in clinical pathology.

(2) One additional year which may be a continuation of the preceding or may be independent practice of both pathologic anatomy and clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board. After July 1, 1953, candidates who elect to claim credit for one year for a clinical internship must take this fifth year as supervised study and training in clinical pathology in institutions approved for residency training in clinical pathology by the Council on Medical Education and Hospitals of the American Medical Association or by the board. Candidates declared eligible after July 1, 1953, who do not take a clinical internship, may, after four years of training as outlined in 2-(1)-(*a*) and (*b*), spend the fifth year in independent practice in an institution or laboratory acceptable to the board.

Note.—As outlined in the preceding paragraphs, the total time requirements of the board are unchanged after July 1, 1953, namely, five years of study or practice after graduation from medical school, with exceptions noted in sections 2-(*a*)-(1) and 2-(*b*)-(1).

3. The specific requirements for those acceptable after eleven years are as follows:

(*a*) The practice of pathology under circumstances acceptable to the board for a period of not less than eleven years. At the election of the candidates, a period not to exceed one year of straight or rotating clinical internship may be substituted for one of the eleven years. For those candidates in this category who have had some special study and training in pathologic anatomy or clinical pathology acceptable under paragraphs 2-(*a*), (*b*) or (*c*), double time credit will be allowed. Thus, if a person has two years of acceptable supervised study and training, only seven years of practice are required.

D. SPECIAL QUALIFICATIONS

1. Prior to Dec. 31, 1947, the board at its discretion certified candidates without examination, if the following conditions were met as of July 1, 1939:

(*a*) That the candidate has been for a period of five years of professorial rank in a department of pathology in an approved medical school; or

(*b*) That the candidate had been practicing pathology for ten years in a senior position in a hospital having an adequate department of pathology, approved by the Council on Medical Education and Hospitals of the American Medical Association or in an institution acceptable to the board.

CREDIT FOR MILITARY SERVICE

Credit may be allowed for training and experience in pathology in the federal services during the period July 1, 1940, to June 30, 1947. This credit for training or experience or both is given on an individual basis and will depend on the opportunity the applicant has had, as indicated by his or her medical service record in the specialty of pathology.

After July 1, 1947, credit for those military services will be given on the same basis as it is in civilian institutions, except that the rule in the preceding paragraph will not apply to reserve officers who continue on active duty or are called to active duty after that date.

SUBSPECIALTIES OF PATHOLOGY
(IN FORCE AFTER JULY 1, 1948)

Candidates who have met all general requirements and who have successfully passed the examination in pathologic anatomy and clinical pathology may apply for special designation of a subspecialty of pathologic anatomy or clinical pathology. The board, at its discretion, may approve this application, and after the candidate has successfully passed a prescribed examination, will issue a certificate designating the subspecialty, reading "Pathologic Anatomy (Neuropathology)," "Clinical Pathology (Clinical Bacteriology)," etc.

Candidates who have met all general requirements and who have had five years of special training and experience in a special field of pathology which is acceptable to the board may apply to the board for certification in that special field. The board, at its discretion, may approve this application, and after the candidate has successfully passed a prescribed examination, will issue a certificate reading "Neuropathology," "Clinical Bacteriology," etc.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary and forwarded with other required credentials and the application fee. An application cannot be given consideration by the board unless it is accompanied by the application fee.

The application or examination fee for candidates is $50. If the candidate fails in his examination he will be admitted to a second examination after one year, but not later than three years, without additional fee. After two reexaminations, the applicant must file a new application and pay an additional fee before a fourth examination will be given.

The application fee of $50 has been determined after careful consideration and is based on actual estimates of the expenses of examination and administration. None of the board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the board, his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the examination.

EXAMINATIONS

Written and oral examinations will be held at the discretion of the board at or near the time and place of national medical meetings. If a number of applications from any region of the country are received, an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examiners will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis, interpretation and technic. The applicant may apply for certification in either pathologic anatomy or clinical pathology or both.

The examinations in pathologic anatomy consist of a written test, an oral examination on gross pathology and a practical examination in microscopic pathology. The examination in clinical pathology consists of a written test and an oral and practical examination in the six phases of clinical pathology: bacteriology, hematology, clinical chemistry, parasitology, serology and clinical microscopy.

DEFINITIONS

1. Pathologic anatomy is that branch of pathology which deals with the morphologic aspects of disease, recognition being given that that definition covers two phases of pathology.

(*a*) The applied phase with special attention to the description and diagnosis of gross and microscopic specimens.

(*b*) The academic phases of teaching and general morphologic diagnosis.

2. Clinical pathology is that branch of pathology which deals with bacteriology, immunology, clinical chemistry, parasitology, hematology, endocrinology and clinical microscopy, the application of the physical and biologic sciences to the diagnosis, prognosis and treatment of disease.

BOARD NOT AN EDUCATIONAL INSTITUTION

The board is in no sense an educational institution and the certificates of the board are not to be considered degrees. Therefore, the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of pathology. The board does not purport in any way to interfere with or limit the professional activities of any licensed physician. Its chief aim is to standardize the qualifications for the specialty of pathology and to issue certificates to those voluntarily complying with the requirements of the board.

CRITERIA FOR APPROVAL OF INSTITUTIONS FOR TRAINING IN PATHOLOGY

In Sections C-2-a, C-2-b, and C-2-c of the General Requirements, it is stated that candidates must have certain periods of supervised study and training. The American Board of Pathology, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, certifies hospitals in the United States as satisfactory for this supervised study and training. Lists of these hospitals are published in the Internship and Residency Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION each year. In addition, the American Board of Pathology recognizes certain hospitals outside the United States and certain laboratories not connected with hospitals in the United States. Inquiries concerning these should be directed to the Secretary of the Board.

The general criteria for approval of hospitals and laboratories are both qualitative and quantitative. On the score of quality, consideration is given to the qualifications of the Director of Laboratories and the associates and assistants, the supervision of work of the person in training, the excellence of the educational program, and the exactness and completeness of the laboratory work performed. On the score of quantity, consideration is given to the volume and distribution of laboratory work, both in absolute numbers and in relation to the size of the hospital, to the diversity and completeness of tests performed, to the size and equipment of the laboratory, and to the number of professional and nonprofessional personnel in relation to the volume of work.

In general, the qualitative standards will determine whether or not a hospital or laboratory is approved, and the quantitative standards will determine whether the approval is for 1, 2, 3 or 4 years of credit toward the requirements of the board.

In evaluation of applications the board takes into consideration the following criteria:

1. Director of laboratories or pathologist:
   - (*a*) It is required that the responsible head of the laboratory hold the certificate of the American Board of Pathology in the subject for which the hospital is approved, or be eligible for certification, and that he or she spend full time in the hospital. Full time is not interpreted in terms of hours, but rather that the director have no obligation outside the one approved hospital except in a university department of pathology where he and the residents have an opportunity to participate in the educational program;
   - (*b*) In special instances, the equivalent of full time by two or more qualified individuals will be accepted and one person need not spend the entire working day in the laboratory;
   - (*c*) In special instances, two or more hospitals will be approved as a unit with a single full-time director of laboratories if it is apparent that a satisfactory training program can be conducted;
   - (*d*) In hospitals with over 350 beds, it is expected that the professional staff, in addition to the pathologist, will include one or more persons with special training and qualifications in the subspecialties of clinical pathology.
2. Technicians:

   There are no absolute criteria, but it is expected that the number of technicians will be proportional to the volume of laboratory work and that, insofar as possible, the technicians will hold the certificate of the Registry of Medical Technologists of the American Society of Clinical Pathologists.
3. Floor space of laboratory:

   In general, it is believed that the size of the laboratory should be related to the size of the hospital and the volume of laboratory work. A minimal ratio is 4 square feet of space in the laboratory, including morgue and autopsy room, for each bed in the hospital.
4. Equipment for the laboratory:

   The variety and completeness of laboratory tests performed depends on the size of the hospital. In all hospitals there should be facilities for the more common tests in clinical pathology, for study of surgical specimens, and for performance of autopsies. In larger hospitals, the variety of tests performed should be larger and in hospitals with over 500 beds all recognized laboratory procedures should be available for study and treatment of the patients.
5. Autopsy percentage:

   No institution with a percentage of less than 15 will be approved, and those institutions with percentages between 15 and 40 will be given special scrutiny.
6. Examination of surgical specimens:

   All surgical specimens should be sent to the laboratory for gross examination, and microscopic examinations should be made unless there are general or special reasons not to do so.
7. Indices:

   There should be indices according to the names of the patients and the diagnoses of all surgical and autopsy material. Indices of clinical pathology are left to the discretion of the hospital.
8. Museum:

   There should be available fixed anatomic and pathologic specimens for study by the staff in proportion to the size of the hospital. Properly filed and indexed color photographs may in part be substituted for museum specimens.
9. Library:

   A reasonably complete library of modern books and recent unbound and bound journals should be available to the hospital, and the more commonly used books and journals should be on hand in the laboratory.
10. Educational program:

    The work of the person in training should be supervised. Conferences, seminars, journal clubs, and demonstrations should be conducted as frequently as the volume of material and the size of the staff justifies. A clinicopathologic conference must be held at least every 2 weeks.
11. Volume of laboratory work:
    - (*a*) As indicated in the following categories, no hospitals with less than 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology annually will be approved (Category D), except as outlined in the following paragraphs. It is the belief of the board that less material than this is inadequate for the training of a pathologist.
    - (*b*) In the field of clinical pathology, there should be a reasonable diversification of tests and in each category there should be sufficient absolute volume to provide training and experience. There are no absolute criteria, but special scrutiny will be given to a hospital in which there is not a reasonable diversification and variety.
    - (*c*) In the field of pathologic anatomy, a deficiency in either autopsies or surgical specimens may be made up by an excess of the other, if the deficiency does not exceed 20 per cent of the minimum required in the ratio of 1 autopsy to 75 surgical specimens. Thus in a hospital approved for one year in pathologic anatomy and clinical pathology, the minimums are 75 autopsies and 1,000 surgical specimens. If a hospital has 2,500 surgical specimens, it is acceptable if there are only 60 autopsies.

If a hospital has met these minimal qualitative and quantitative standards, it will then, on the basis of the following quantitative standards, be approved for 1, 2, 3 or 4 years of training in pathologic anatomy, or clinical pathology, or both, or some special field as shown for the number of residents indicated.

CATEGORY A. In both pathologic anatomy and clinical pathology for 4 years (as required of all candidates seeking certification in both fields who are examined after July 1, 1952).

Minimum: 150 autopsies, 1,750 surgical specimens, and 65,000 tests in clinical pathology for 4 residents. Additional resident for each 50 autopsies or 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY B. In both pathologic anatomy and clinical pathology for 3 years. This meets all requirements of the board for supervised training until July 1, 1952. Candidates examined after that date who seek certification in both subjects must take an additional year of supervised training in clinical pathology or pathologic anatomy, in another hospital, which is approved for the deficiency of training required.

Minimum: 125 autopsies, 1,500 surgical specimens and 50,000 tests in clinical pathology for 3 residents. Additional resident for each 50 autopsies, 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY C. In both pathologic anatomy and clinical pathology for 2 years. Candidates taking two years in these institutions must have an additional year (2 years after July 1, 1952) in an institution in category A, B or D.

Minimum: 100 autopsies, 1,250 surgical specimens, and 40,000 tests in clinical pathology for 2 residents. Additional resident for each 50 autopsies, or 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY D. In both pathologic anatomy and clinical pathology for 1 year. Candidates taking training in these institutions must have an additional 2 years (3 years after July 1, 1952) in institutions which are approved for the deficiency of training required.

Minimum: 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology for 1 resident. Additional resident for each 50 autopsies, or 500 surgical specimens, or 20,000 tests in clinical pathology.

Category E. In pathologic anatomy only, for 3 or more years. Candidates taking all training in these institutions will not be eligible for certification in clinical pathology unless an additional year (2 years after July 1, 1952) is taken in clinical pathology in institutions which are approved for the deficiency of training required.

Minimum: 175 autopsies and 1,500 surgical specimens for 3 residents. Additional resident for each 50 autopsies or 500 surgical specimens.

Category F. In pathologic anatomy only, for 2 years. Candidates taking training in these institutions will not be eligible for certification in clinical pathology unless they take one additional year full time in clinical pathology (2 years after July 1, 1952) in institutions which are approved for the deficiency of training required, and will be eligible in pathologic anatomy only if another year is taken in another institution which is approved for one or more years in pathologic anatomy.

Minimum: 125 autopsies and 1,250 surgical specimens for 2 residents. Additional resident for each 50 autopsies or 500 surgical specimens.

Category G. In pathologic anatomy only, for 1 year. Candidates training in these institutions will not be eligible in both pathologic anatomy and clinical pathology unless they take an additional year in pathologic anatomy and an additional year (2 years after July 1, 1952) in institutions which are approved for these periods of training. Candidates seeking certification in pathologic anatomy only must study an additional 2 years in institutions which are approved for that period of training.

Minimum: 75 autopsies and 1,000 surgical specimens for 1 resident. Additional resident for each 50 autopsies or 500 surgical specimens.

Category H. For postmortem part of pathologic anatomy for 2 years. Credit is never allowed for more than 2 years. Candidates taking training in these institutions may pursue further training as follows: 1. For pathologic anatomy only. An additional year in an institution in Category A, B, C, E, F or G with assignment to surgical pathology principally. 2. For pathologic anatomy and clinical pathology. An additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M or N with assignment to clinical pathology and ½ year assigned to surgical pathology principally, in an institution in Category A, B, C, or J.

Minimum: 125 autopsies for 2 residents. An additional resident for each 60 autopsies.

Category I. For postmortem part of pathologic anatomy for 1 year. Candidates taking training in these institutions may pursue further training as follows: 1. For pathologic anatomy only. An additional two years in an institution in Category A, B, C, E, F or G with general assignments. 2. For pathologic anatomy and clinical pathology. An additional year (2 years after July 1, 1952) in an institution in Category A, B, C, L, M or N with assignment to clinical pathology and 1 year to an institution in Category A, B, C, E, F or G.

Minimum: 75 autopsies for 1 resident.

Category J. Surgical pathology part of pathologic anatomy for 1 year. Credit is never allowed for more than 1 year and the director of the laboratory must hold the certificate of the American Board of Pathology in pathologic anatomy or be eligible for certification. Candidates training in these institutions may pursue further training as follows: 1. For pathologic anatomy only. An additional 2 years in an institution in Category H or in an institution of Category A, B or C with assignment to postmortem pathology only. 2. For pathologic anatomy and clinical pathology. An additional year (2 years after July 1, 1952) in an institution in Category A, B, C, L, M or N with assignment to clinical pathology full time, and an additional year to an institution in Category A, B, D, E, F, G or H with assignment to postmortem pathology full time.

Minimum: 2,000 surgical specimens for 1 resident. An additional resident for each 1,000 surgical specimens.

Category K. Special pathology as part of pathologic anatomy. Credit for not to exceed ¼ the time credit (1 year if seeking certification in pathologic anatomy only, 6 months if seeking both pathologic anatomy and clinical pathology) of candidates applying in pathologic anatomy may be taken in special laboratories with limited activities such as neuropathology, orthopedic pathology, ophthalmic pathology, etc. The candidate who receives credit in this category may, on request, have the field of special pathology designated on the certificate of the board.

Category L. Clinical pathology for 3 or more years. Candidates taking 3 years of training in these institutions will not be eligible for pathologic anatomy unless they take an additional 2 years in institutions approved for pathologic anatomy.

Minimum: 100,000 tests in clinical pathology for 3 residents. Additional resident for each 50,000 tests.

Category M. Clinical pathology for 2 years. Candidates taking two years' training in these institutions must take the same additional training as in Category L to be eligible for pathologic anatomy also. To be eligible for clinical pathology only, an additional year of clinical pathology must be taken in an approved institution.

Minimum: 75,000 tests in clinical pathology for 2 residents. An additional resident for each 50,000 tests.

Category N. Clinical pathology for 1 year. Candidates taking training in those institutions must take an additional 2 years in an institution in Category A, B, C, L or M assigned to clinical pathology for eligibility in clinical pathology only. To be eligible in pathologic anatomy and clinical pathology, an additional 2 years in approved institutions is required.

Minimum: 50,000 tests in clinical pathology for 1 resident.

Category O. Special clinical pathology as part of clinical pathology. Candidates applying for clinical pathology only may receive credit for not in excess of ¼ of the training period (1 year if seeking certification in clinical pathology only, six months if seeking both pathologic anatomy and clinical pathology) for work in a special field of clinical pathology, such as bacteriology, serology, etc. Under these circumstances, on request, the special field will be designated on the certificate of the board.

Category P. Research: Residence in certain institutions in which full time is devoted to research with a direct application to the practice of pathologic anatomy or clinical pathology may be accepted for credit not to exceed one-third the time requirement (20 months if no clinical internship, 16 months if a clinical internship was taken). The board encourages research and believes that all candidates should carry on investigation during their training in all institutions. Therefore, this category is only for those wishing to do full time research.

AMERICAN BOARD OF PEDIATRICS

Lee Forrest Hill, President, Des Moines, Iowa.
A. Ashley Weech, Vice-President, Cincinnati.
Henry G. Poncher, Secretary-Treasurer, Chicago.
James G. Hughes, Memphis.
A. Wilmot Jacobsen, Buffalo.
J. A. Johnston, Detroit.
Waldo E. Nelson, Philadelphia.
Arthur H. Parmelee, Beverly Hills, Calif.
Ralph V. Platou, New Orleans.
John McK. Mitchell, Executive Secretary, 6 Cushman Road, Rosemont, Pa.

REQUIREMENTS FOR CERTIFICATION [1]

All candidates for examination for certification must meet the following requirements:

1. Graduation from an approved medical school.
2. One year of rotating, pediatric or other internship in an approved hospital.

---

[1] To avoid misunderstanding, the board urges any candidate whose training is not clearly covered in these regulations to communicate with the office of the executive secretary. Whenever possible, this should be done before entering upon the appointment in question.

3. Two years of specialized residency-type training in an approved pediatric center.

On May 1, 1946, it was ruled that at least one year of the two years of required residency training must be a full time medical pediatric in-patient residency or internship in an approved institution. Because of the shortage of residencies, the board at this time voted that "temporarily" the second year of required residency training might be met in the ways listed below, although the board recommends that whenever possible candidates complete the two years as regular residents.

(a) All applicants admitted to approved graduate or postgraduate courses in pediatrics on or after July 1, 1950, shall receive residency training credit for that number of months actually spent in full time attendance at such courses, in excess of three months and up to a maximum of twelve months. No credit shall be granted for part time graduate or postgraduate courses. Courses of less than three months are credited only under special circumstances.

(b) A maximum of three months' credit each is allowed for full time residency type training in allied pediatric subjects, such as pediatric allergy, pediatric psychiatry, pediatric pathology, pediatric cardiology, newborn service, etc.

(c) A maximum of six months' credit is allowed for residency training in an approved contagious disease hospital.

4. A subsequent term of two years of specialized study or practice or a combination of the two. Credit for one year toward this requirement is allowed for medical military service regardless of the assignment. Credit in excess of one year may be granted if the medical officer is engaged in full-time pediatrics, or may be prorated if a considerable proportion of time is spent in pediatrics. It must be noted, however, that the maximum credit that any candidate may receive toward the practice requirement for work done prior to the completion of residency training is one year.

Attention is invited to the fact that the primary duty of the resident must be the care of patients under supervision, if full credit in satisfaction of the residency training requirement is expected. Research residencies which involve little or no clinical training are creditable for only three months. Research residencies which include significant clinical training may be prorated to a total of six months for a year of service. Teaching fellowships may not be offered in lieu of residency appointments.

Both research residencies and teaching fellowships are, of course, entirely acceptable in satisfaction of the practice or further study requirement. Portions of a research residency not applicable for residency training credit may be carried over for practice credit.

Preceptorships are not accepted for credit toward the residency requirement, but are accepted toward the practice requirement.

The board defines service in a pediatric center as full time devoted to rounded experience in an approved hospital which includes responsibility for care of patients on ward and outpatient services, experience with newborn, including prematures, and both therapeutic and preventive pediatrics. It is expected that the service will include adequate graduate training in the basic medical sciences, as well as in the clinical, laboratory and public health aspects of the specialty.

INFORMATION CONCERNING EXAMINATIONS

The examinations for certification are given in two sections: Part I is written; Part II is an oral examination.

PART I—WRITTEN

Written examinations are objective in type and are given once each year, usually in January, simultaneously at a number of places scattered throughout the country. Effective Jan. 1, 1953, candidates must pass the written examination before admission to the oral examination will be authorized. In case of failure, the written examination may be retaken at yearly intervals for a total of three times.

PART II—ORAL

Oral examinations are held four to six times each year at centers offering suitable facilities, in locations determined by proximity to the largest number of eligible candidates. One examination session each year is scheduled at a location closer to candidates from some less populous area. As far as possible, candidates are given a choice of location, taking into account date application is filed, date of eligibility and proximity to the examination site.

APPLICATION

Application must be made on special blanks which will be furnished by the executive secretary after a preliminary survey of the applicant's training. Applications may be submitted one year in advance of eligibility date, they will not be accepted earlier. The number of candidates admitted to a given written examination will be determined by the number who can be examined orally during that year, plus a reasonable number of alternates. The January, 1952, written examination list was filled by September, 1951.

FEES

The application fee is $100.00.

The full fee must be remitted with the application. Refund will be made only if the applicant is refused examination for reason other than failure in the same.

No additional fee is required for second and third written examinations. The fee for second and third oral examinations is $50.00 each.

Members of the board receive no financial recompense of any kind beyond their travel expenses to examinations and board meetings.

FAILURE IN EXAMINATIONS

As indicated above, a written examination must be passed before a candidate is eligible for oral examination. Reexaminations may be taken one and two years later. After a third failure, the situation will be reviewed by the board and a decision concerning subsequent procedure will be made.

Applicants who fail an oral examination become eligible for a second examination after a year has elapsed. After a second failure another examination will be permitted in one year. Before becoming eligible for a fourth examination a candidate must serve one year in a full-time medical inpatient residency in an approved institution. He must then reapply as a new candidate and pay a new fee.

LETTERS OF RECOMMENDATION AND BIBLIOGRAPHY

Letters from two competent pediatricians recommending each applicant must be sent to the executive secretary of the board. These letters should not accompany the application, but should be sent directly to the executive secretary. No member of the board, or official examiner, may recommend any applicant.

A list of papers or books published should be sent in with the application blank.

PURPOSE OF EXAMINATIONS

The purpose of these examinations is to determine the applicant's competency to practice pediatrics of high quality. Emphasis is therefore placed on practical aspects, but since good practice is founded on sound scientific data, the candidate must be prepared to demonstrate that he has a working knowledge of these basic data.

Clinical and abstract aspects of growth and development are fundamental parts of pediatric training, and about one-fourth of the oral examination is devoted to this phase of the subject. Diagnosis and treatment of disease fill another quarter, and the remainder of the examination is devoted to study and discussion of "cases."

Candidates who are admitted to the oral examination (Part II) will not be informed of their grade on the written portion. Their relative standing in Part I will, however be utilized in the final decision with regard to passing.

Candidates who fail after taking Part II will not be required to retake Part I but may be advised to do so in order that they may have an opportunity to improve a low score.

CERTIFICATE—NOT A DEGREE

Certificates granted are in no sense degrees, nor do they purport to confer on any person any legal qualification, privilege or license to practice pediatrics. Neither does the board intend in any way to limit the activities of any licensed physicians. It is merely attempting to standardize qualifications and to issue certificates to those who voluntarily comply with the requirements. Hence the fact that a physician holds a certificate of the board places no obstacle in the path of participation in community or hospital emergency coverage plans, nor does it place any restriction on holding the certificate of another board.

CERTIFICATION IN SUBSPECIALTY OF ALLERGY BY THE AMERICAN BOARD OF PEDIATRICS, INC.

MEMBERS—SUBSPECIALTY BOARD OF PEDIATRIC ALLERGY

William P. Buffum, Chairman, Providence, R. I.
William C. Deamer, San Francisco.
Jerome Glaser, Rochester, N. Y.
James Overall, Nashville, Tenn.
Bret Ratner, New York.
Albert Stoesser, Minneapolis, Minn.

The American Board of Pediatrics, Inc., has established certification in allergy as a subspecialty of pediatrics.

All candidates must pass the written and oral examinations in pediatrics before submitting an application for examination in allergy.

Each allergy application is individually considered and must be accepted by the subspecialty board.

INFORMATION CONCERNING EXAMINATIONS

Allergy examinations consist of written and oral portions. The written examination will be given once a year under a local monitor and must be passed before admission to the oral examination will be authorized. Oral examinations will be held at times and places designated by the Chairman of the Subspecialty Board. Ample notice will be sent to candidates by the executive secretary.

FAILURE IN EXAMINATIONS

As indicated above, a written examination must be passed before a candidate is eligible for oral examination. Reexaminations may be taken one and two years later. After a third failure, the situation will be reviewed by the board and a decision concerning subsequent procedure will be made.

Applicants who fail an oral examination become eligible for a second examination after a year has elapsed. After a second failure another examination will be permitted in one year. Before becoming eligible for a fourth examination a candidate must serve one year full time in a satisfactory allergy clinic and its hosptials including training in both allergy and pediatrics.

FEES

The application fee for certification in allergy will be $100.00 effective July 1, 1952.

The full fee must be remitted with the application. Refund will be made only if the applicant is refused examination for reason other than failure in the same.

No additional fee is required for second and third written examinations. The fee for second and third oral examinations is $50.00 each.

Members of the board receive no financial recompense of any kind beyond their travel expenses to examinations and board meetings.

Application forms will be forwarded on request to the office of the executive secretary and should be returned to that office when completed. All correspondence should be addressed to him.

REQUIREMENTS

1. Completion of two years of approved residency training in pediatrics.

2. Two years full time in a satisfactory allergy clinic and its hospital, including training in both allergy and pediatrics, or

3. One year full time in a satisfactory allergy clinic and its hospital, and two additional years of full attendance in a satisfactory allergy clinic and its activities, or

4. Five years attendance of not less than 300 hours per year at an allergy clinic associated with an approved medical school or in hospital clinics specifically approved for this purpose.

5. Preceptorship training alone is not acceptable. It may be utilized in combination with the methods outlined in paragraphs three and four above or with a full time formal graduate or postgraduate course in allergy to satisfy portions of the second and third years in three, or one of the five years in four.

The clinics should be in hospitals that have been accepted by the Council on Medical Education and Hospitals of the American Medical Association, and by the American Board of Pediatrics for training and certification in Pediatrics.

In general, a satisfactory allergy clinic is one which is headed by a certified allergist.

Under all methods of study, there must be presented evidence of serious work in research or clinical investigation, to demonstrate interest and industry in the study of allergy.

NATURE OF EXAMINATIONS

The candidates must expect a searching examination in both the theory and practice of allergy. This means that they must come prepared to do physical examinations on selected patients, take histories, and to discuss all details in diagnosis and treatment on the patients that have been assigned to them. In addition they may be called upon to discuss any theoretical question that the examiners may choose to bring up.

CERTIFICATE

When accepted the diplomate will receive from the American Board of Pediatrics a certificate in allergy and will be listed as a specialist in allergy.

Prospective applicants for certification in the subspecialty of allergy may apply to the executive secretary of the American Board of Pediatrics.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION

Robert L. Bennett, Chairman, Warm Springs, Ga.
William H. Schmidt, Vice Chairman, Philadelphia.
William Bierman, New York.
Donald A. Covalt, New York.
Kristian G. Hansson, New York.
O. Leonard Huddleston, Santa Monica, Calif.
A. B. C. Knudson, Washington, D. C.
Walter M. Solomon, Cleveland.
Arthur L. Watkins, Boston.
Walter J. Zeiter, Cleveland.
Earl C. Elkins, Secretary-Treasurer, 30 North Michigan Ave., Chicago 2.

QUALIFICATIONS FOR ELIGIBILITY TO EXAMINATION FOR CERTIFICATION

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

1. GENERAL

A. Satisfactory moral and ethical standing in the profession.

B. Membership in the American Medical Association or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. (Exceptions to the foregoing qualifications shall be made by the American Board of Physical Medicine and Rehabilitation for good and sufficient reasons.)

2. PROFESSIONAL

A. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

B. Completion of an internship, preferably of the general rotating type, of not less than one year in a hospital approved by the same council.

3. SPECIAL TRAINING

A. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council and by the American Board of Physical Medicine and Rehabilitation as competent to provide a satisfactory training in physical medicine and rehabilitation. Each year of training in such an approved program counts as two units against a total of eight units necessary for eligibility to both Parts I and II of the examination (see below). A total of only six credits may be earned in this manner.

B. This period of specialized preparation shall include: (1) graduate training in anatomy (including kinesiology and functional anatomy), physics (including radiation physics, electronics and medical instrumentation), physiology, pathology and other basic sciences which are necessary to the proper understanding of physical medicine and rehabilitation; (2) an active experience of not less than two years in hospitals, clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals and the American Board of Physical Medicine and Rehabilitation; (3) the written and oral examinations, given by the American Board of Physical Medicine and Rehabilitation, shall include questions concerning the basic sciences, clinical practice and laboratory and public health problems as related to physical medicine and rehabilitation.

C. An additional period of not less than two years of practice in physical medicine and rehabilitation. One unit of credit is granted for each year of practice in physical medicine and rehabilitation.

D. Experience comparable to specialized training. Training in approved residency programs in closely allied medical surgical fields may be acceptable in whole or in part, but maximum credit is limited to two units. In selected cases, at the discretion of the Board, two years of specialization in physical medicine and rehabilitation may be accepted as equivalent to one year formal training.

METHOD OF EXAMINATION

The examination for certification by the American Board of Physical Medicine and Rehabilitation is given in two parts. Part I is written, Part II, oral. Part I alone may be taken after the completion of six units of credit. Upon the completion of Part I, Part II may be taken after an additional two units of credit are obtained. Parts I and II combined may be taken only after a total of eight units of credit have been obtained.

The written and oral examination will cover certain aspects of the basic sciences as well as clinical physical medicine and rehabilitation.

A. The basic sciences as related to physical medicine and rehabilitation will include:

(*a*) Anatomy (including kinesiology and functional anatomy).

(*b*) Physics (including radiation physics, electronics and instrumentation).

(*c*) Physiology (including physiology of movement and physiologic effect of the various physical agents used in physical medicine and rehabilitation).

(*d*) Pathology.

(*e*) Other fundamental sciences. The applicant will be examined concerning his knowledge of such subjects as biochemistry and bacteriology as related to physical medicine and rehabilitation.

B. The clinical aspects of physical medicine and rehabilitation will include:

(*a*) Those diseases and conditions that come within the field of physical medicine and rehabilitation. These include arthritis and the various rheumatic diseases, neuromuscular diseases such as poliomyelitis, cerebral palsy, and paraplegia, and musculoskeletal diseases, including the large group of traumatic and orthopedic conditions.

(*b*) The clinical usage of such physical agents as heat, water, electricity, ultraviolet radiation, massage and exercise, etc.

(*c*) An understanding of the basic principles of physical medicine and rehabilitation and the ability to coordinate the services of such personnel as clinical psychologist, social service worker, vocational guidance worker, etc.; the ability to prescribe specifically the therapy for patients for execution by the technical and ancillary personnel in a department of physical medicine and rehabilitation.

(*d*) A knowledge of the use of associated personnel within the field of physical medicine and rehabilitation such as the physical therapist, occupational therapist, clinical psychologist, and social service worker. This knowledge must include the ability to specifically prescribe patient care for execution by these therapeutic and technical groups.

APPLICATION

The application form shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital or dispensary staff appointments, teaching positions, length of time practice has been limited to physical medicine and rehabilitation, membership in medical societies, medical papers published, and the names of three well known physicians to whom the board may write for professional and character references. Three letters of reference must be submitted with the application.

The application shall also be accompanied by one recent signed photograph of the candidate mounted on the application and the registration and examination fee of $100, which fee will cover both the written and oral examinations. (In case of rejection of application, this fee will be refunded with the exception of $15, which will be considered as a registration fee.)

CERTIFICATES

The certificate issued by the American Board of Physical Medicine and Rehabilitation shall be in such form as to comply with the articles of incorporation and bylaws and shall be signed by the chairman and the secretary-treasurer of the board and shall bear the official seal of the board.

Certificates of the board shall be issued to the effect that the applicant has been found qualified to practice physical medicine and rehabilitation.

AMERICAN BOARD OF PLASTIC SURGERY

WALLACE H. STEFFENSEN, Chairman, Grand Rapids, Mich.
JAMES T. MILLS, Vice Chairman, Dallas, Texas.
WILLIAM MILTON ADAMS, Memphis, Tenn.
GUSTAVE AUFRICHT, New York.
LOUIS T. BYARS, St. Louis.
ALBERT D. DAVIS, San Francisco.
S. MILTON DUPERTUIS, Pittsburgh.
FREDERICK A. FIGI, Rochester, Minn.
PAUL W. GREELEY, Chicago.
WILLIAM G. HAMM, Atlanta, Ga.
WILLIAM F. MACFEE, New York.
GERALD B. O'CONNOR, San Francisco.
A. NEAL OWENS, New Orleans.
CLARENCE R. STRAATSMA, New York.
BRADFORD CANNON, Secretary-Treasurer, 330 Dartmouth St., Boston 16.
ESTELLE E. HILLERICH, Corresponding Secretary, 4647 Pershing Ave., St. Louis 8.

REQUIREMENTS

GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Those whose activities are limited to the practice of plastic surgery.

3. This board will accept as applicants for examination only those who are full citizens of the United States or Canada. Notarized statements, not original citizenship papers, attesting to the fact of full citizenship in the United States or Canada must

be furnished by foreign born applicants when the application is filed. Such candidates must have at least two years of practice in plastic surgery in North America after completing the training required by the board.

PROFESSIONAL REQUIREMENTS FOR QUALIFICATION

The board considers the requirements outlined below to be minimal in attaining its purposes, and encourages candidates to take advantage of broadening experience in other fields. Candidates must fulfill the requirements which are in force at the time of their examination and/or certification.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered acceptable by the board.
2. Completion of an internship of not less than one year in a hospital approved by the same Council, or what would constitute in the opinion of the board the equivalent of such training.
3. Two years of postgraduate work in general surgery beyond the intern year, as a resident or an assistant resident in an approved hospital, or a period of training gained elsewhere judged by the board to be the equivalent of such training.
4. Training in general plastic surgery (including maxillofacial surgery) in an acceptable residency [1] or preceptorship for an additional period of not less than two years, also be taken in an approved hospital,[1] or under auspices satisfactory to this board.
5. During these years of training following the internship year, a candidate must hold positions of increasing responsibility for the care and management of patients with surgical conditions. When a candidate receives his training in more than one institution, it is equally imperative that he hold positions of increasing responsibility. He must have sufficient operative experience to acquire surgical skill and judgment through the performance of surgical operations with a high degree of responsibility, but under circumstances providing adequate opportunity for consultation and advice.
6. An additional period of not less than two years of practice in plastic surgery. If a candidate elects to spend one or two additional years in approved training in plastic surgery, one year of such training will be credited toward the required two years of private practice if it can be demonstrated that the candidate held a position of increasing responsibility. It is imperative that one year be in actual private practice in such instances.

The above training may be taken as a resident in surgery and in plastic surgery in an approved hospital, or under a preceptorship offering equivalent training. By the latter statement it is meant that one may secure the necessary and specified training as an assistant to an accredited surgeon providing suitable facilities for the education of the candidate are offered.

The period of special training should emphasize the relation of the basic sciences—anatomy, pathology, physiology, biochemistry, bacteriology—to the application of surgical principles which are fundamental in all branches of surgery, and especially to plastic surgery. In addition, the candidate must understand and be trained in the following subjects: the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

Because of vagaries of training, such as changes from one specialty to another, interims of military duty and other service to the country, the aptitude and skill of candidates, the board may, at its discretion, review and make recommendations for or against certification of certain applicants outside of the listed qualifications and requirements.

The board reserves the privilege of requesting lists of operations done solely by the candidate for one or more years, or of requesting special and extra examinations, written or oral and practical, and of requesting any specific data concerning the candidate that may be deemed advisable before making final decision for certification.

Eligibility rulings or an evaluation of a candidate's qualifications or training cannot be made by the secretary or by any one member of the board. Official evaluations of qualifications are made only by the Committee on Credentials and Requirements, or by the entire board where necessary, after a review of the candidate's formal application for such rulings. The applicant must allow at least four weeks for such requests to make the rounds of the committee.

TRAINING FACILITIES

The American Board of Plastic Surgery, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association and the American College of Surgeons, evaluates training facilities in institutions providing acceptable residencies in plastic surgery. Neither the board nor its individual members can be responsible for the placing of applicants for training. The board will give no independent approval and will keep no independent list of approved residencies or preceptorships. The board will consider those residencies approved by the Council on Medical Education and Hospitals of the American Medical Association as acceptable facilities for training in plastic surgery.

For the time being, it is felt that too few residencies in plastic surgery exist to meet the training needs. In certain instances the board will accept, in lieu of the required two years' training in an approved residency, training in a preceptorship under a fully qualified plastic surgeon when such preceptorship is properly organized and supervised to give the trainee adequate experience and training in plastic surgery of a well-rounded nature. Certain established preceptorships are given full approval. New preceptorships will be given tentative approval in advance on presentation to the board by the preceptor of a well-rounded plan of training. In such instances the trainee will be required to keep a record of his experience. In tentatively approved preceptorships it would be well for a preceptor to report annually to the board the name and qualifications of any preceptee under his supervision, as well as the work done by the preceptee. The preceptee should report to the board every six months the number and type of operations performed both under supervision and independently, giving details of supplementary activities of his training. If the preceptorship is found to be adequate in scope, it will be transferred to the fully approved list. All those training in preceptorships must submit six month reports of their work.

It should be kept in mind by all that the primary interest of the board is to encourage well rounded training in plastic surgery with the aim of producing plastic surgeons capable of doing good work in the wide variety of cases which may come under their care. The standards set up by the board, both for preliminary general surgery and for specialized plastic surgery training, are established in an effort to further this aim. The quality of the training received should be reflected in the candidate's ability to achieve good results in his practice and the examinations of the board are an attempt to judge the ability of the candidate in the specialty of plastic surgery.

SUGGESTIONS FOR TRAINING IN PLASTIC SURGERY

A residency in plastic surgery is one in which a hospital appointment for training in plastic surgery is given the trainee. In a preceptorship in plastic surgery no such appointment is given.

While the board permits flexibility in training, approved residencies and preceptorships should be under fully qualified plastic surgeons. Those trained in preceptorships will be judged by the candidate's ability to make the most of his training and to show adequate ability in all phases of the subject.

There must be teaching in either a residency or a preceptorship—instruction in the basic sciences and in the basic principles of plastic surgery—if not in actual courses, then by conferences, ward rounds, lectures by men on the service or other services, or by visiting doctors.

A resident or assistant resident in plastic surgery should have a full time appointment from an A. M. A. Council-approved hospital or hospitals. A preceptee does not have such an appointment. A residency should preferably be in connection with a teaching hospital having medical school affiliations or be under the Dean's Committee of Veterans Administration hospitals. An acceptable residency is one that is approved by the Council on Medical Education and Hospitals of the American Medical Association.

---

[1] An acceptable residency is one which has been approved by the Council on Medical Education and Hospitals of the American Medical Association.

Before training in plastic surgery is begun, the plastic surgeon in charge of the residency or preceptorship should ascertain that the trainee's preliminary training in general surgery meets the requirements of the board, that is two years of residency training in general surgery after the internship year.

The training in plastic surgery (at least two years) whether in a residency or a preceptorship, should cover a wide field of plastic and maxillofacial surgery, both as to type and anatomical distribution. There should be available sufficient material of a diversified nature so that the trainee will be able to pass the examinations of the board after the period of training and the two additional years of private practice. If the available material on one service is inadequate, the deficiency should be made up by affiliation with another plastic surgeon on another service so that a broad experience will be obtained in plastic surgery. The trainee should be provided an opportunity to operate under the direct supervision of the plastic surgeon in charge, and with increasing ability, to be given an opportunity to operate independently on suitable cases under more remote supervision.

RESIDENCY INFORMATION SERVICE

The Council on Medical Education and Hospitals of the American Medical Association maintains a "Residency Information Service," published semiannually, giving lists of available residency appointments in approved services in the specialties. This bulletin, showing available openings in residency appointments in plastic surgery, and other specialties, may be had on request from the Council.

MILITARY CREDIT

Credit for military service is given on an individual basis, each case being considered on its own merits and the amount of credit allowed is determined by the board when the information is submitted with the application.

MEDICAL OFFICER'S PROFESSIONAL TRAINING RECORD

The Medical Officer's Professional Training Record (DD Form 408) is a record maintained by individual Medical Corps officers for presentation to the various authorized accrediting boards toward certification. This record is presented by the officer to the boards for evaluation of the military experience acquired by Medical Corps officers while serving in the Army Medical Service. This form has been prepared by the Surgeons General of the armed services with the assistance of the Council on Medical Education and Hospitals of the American Medical Association and is distributed by the offices of the Surgeons General to their personnel. It is highly important that prospective applicants obtain a copy of this form and that it be submitted with their credentials for evaluation by the board.

CASE REPORTS

On approval by the board of a candidate's application for certification, each candidate is required to submit to the board thirty-five or more case reports illustrative of his independent work in the field of general plastic surgery. Case reports must be submitted within one year from the time of such request; otherwise a new application must be filed. These case reports shall conform to conditions which the board may from time to time specify and the case reports must be approved by the board before the candidate is admitted to examination. **Case reports must be received in the Office of the Board by Jan. 1 for those who desire to be considered for the spring (May-June) examinations of the board and by June 1 for the fall (October-November) examinations. There will be no exceptions to these two deadlines.**

The thirty-five case reports must be of a diversified nature and must be submitted to the office of the board, together with photographs. **To be accepted, case reports must be assembled according to the following instructions.** The group must include a variety of material from the entire body rather than a number of cases of one type, and should carry the candidate's personal deductions, conclusions and comments and should be sufficiently detailed to show if the conclusions drawn indicate a grasp of the subject and if the results justify the procedure.

Each case report should be individually assembled, typed on letter-size paper (8½ by 11 in.), with the candidate's name and the number of the case on each page. Each report should have a cover-sheet with the candidate's name, the number of the case, hospital number, diagnosis and a brief summary of the case. The pages of each report should be stapled together securely and placed in a letter-file folder, not heavier than the ordinary manila file-folder. Do not use paper clips or fasteners. Photographs of conditions and drawings of operative technique, illustrative of each case, should be included and securely attached to each case report, with the name of the candidate and the number of the case indicated. Cases should be chosen from the private practice of the candidate or from the hospital or clinic service. The initials, color, age and occupation of each patient should be stated, as should the name of the hospital where treated and dates of admission, operation and discharge. The important details of family history, if relevant, and of the previous history should be given. The history of the condition for which the patient consulted candidate should be stated clearly and concisely, indicating previous treatment, if any, and the mental, social or economic factors involved. The physical examination of the patient with special reference to the existing deformities should be carefully described. All laboratory and other special examinations, such as roentgenograms, which were made, should be reported, with a statement of what was determined by them. The indications for operation and for the type of operation employed should be given, and the preliminary treatment and the type of anesthesia used should be stated. A full description of the operative technique with methods of hemostasis, suture and drainage, if any, and the name of the assistant should be given. The late and early postoperative course and results should be described. Before and after photographs should be submitted, and all photographs should be uniform in size, not less than 3 by 4 in. (Kodachrome transparencies not acceptable), mounted on a sheet 8½ by 11 in. (letter-file folder weight), made by a sharp focus lens from untouched negatives with identical lighting conditions, exposure and developing, not reversed, to show conditions before and after operations with clear detail.

If the case reports, and lists of operation when requested, are approved, the candidate will receive subsequent information regarding taking the examinations. The board at its discretion may request certification of case reports by the hospital where the operations were performed. The following form should accompany the case reports: "I hereby certify that the planning and essential surgical procedures described herein were carried out by me as an independent operator."

Every candidate's final acceptability for examination is based not only on the evaluation of his training qualifications but on his professional ability as a plastic surgeon, his ethical standing in the community, and the strict limitation of his work to plastic surgery.

A candidate should remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his ability.

EXAMINATIONS

The qualifying examinations are divided into two parts, the written examination, and the oral and practical examination.

The examinations are given twice yearly, in the spring and fall. The spring examination is given immediately preceding, during or following the annual meeting of the American Association of Plastic Surgeons (usually in May), and the fall examination is given immediately preceding, during, or following the annual meeting of the American Society of Plastic and Reconstructive Surgery (usually in October). Candidates are required to go to the designated center for the qualifying examination, which lasts three days. These centers will be the city in which the meetings of these two organizations are held if the proper clinic and hospital facilities are available, otherwise in some nearby city where such material is available. Arrangements for all examinations are made by the Examination Committee.

The written examination will consume all of the first day and half of the second day. The oral and practical examination will consume the afternoon of the second day and all of the third day.

The subjects of the written examination are, (1) theory and practice of plastic surgery, (2) applied anatomy, applied physiology, (3) pathology, bacteriology, clinical laboratory methods, (pharmacology), (4) reaction of tissue to injury, surgical accidents, anesthesia.

A general oral examination pertaining to plastic surgery will be given. In the practical part of the examination, the examiners will present a group of patients for examination by the candidates, and the candidates will be quizzed on methods of procedure—diagnosis, treatment, technic, and so on. Slides of preoperative conditions will be shown on a screen and the candidate asked to make a quick diagnosis of the items and tabulate in the order of their importance and methods of treatment. Microscopic slides of the average pathological tissue falling within the province of the plastic surgeon will be given the candidates on which they will be asked to write a description and diagnosis.

Prior to the examination, the candidate will be visited at his place of practice by a member or members of the board to observe him operate and to examine a number of his pre- and postoperative cases.

To be considered as passing, the candidate will be required to receive a grade of at least 65 per cent in each portion of the written examination and an average of 75 per cent on the entire written and oral examination.

REEXAMINATIONS

Candidates who have failed in any portion of the examination may be admitted to another examination after one year, or within three years, except in such cases as the board may for good and sufficient reason deny a candidate the privilege of reexamination. A candidate who fails one reexamination will be admitted for further examination only after submitting evidence of additional study and preparation. The candidate must give 60 days' notice requesting reexamination and pay a fee of $25.00 for the written examination and $25.00 for the oral and practical examination. The examiners conducting the first examination will not be eligible to conduct the reexamination.

CERTIFICATION

After a candidate has met the requirements for eligibility and passed the examinations of the board, a certificate attesting his qualifications in plastic surgery will be issued to him by the board, signed by its officers and having the seal of the board affixed thereto. It shall be the prerogative of the board to determine the fitness professionally and ethically of any candidate for its certificate, and the action or decision of the board regarding the certification of any candidate shall be final.

The board is in no sense an educational institution and the certificates of the board are not to be considered as degrees. Therefore the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of plastic surgery. The board does not purport in any way to interfere with or limit the professional activities of any licensed physician nor does it desire to interfere with any practitioners of medicine in any of their regular or legitimate activities.

The American Board of Plastic Surgery has never been concerned with measures that might gain special privileges or recognition for its certificants in the practice of plastic surgery. It is neither the intent nor has it been the purpose of the board to define requirements for membership on the staffs of hospitals. The prime object of the board is to pass judgment on the education and training of broadly competent and responsible plastic surgeons—not who shall or shall not perform plastic surgical operations. The board specifically disclaims interest in or recognition of differential emoluments that may be based on certification.

FEES

The fee for application and examination is $150. Of this sum, $25 must accompany the application and the remaining $125 must be paid when the candidate is notified of acceptance for examination. There will be no refunds. This fee may be increased at the discretion of the board. The board is a nonprofit organization and the fees of candidates are used solely for defraying the actual expenses of the board. The members of the board serve without remuneration. Because of the limited number of surgeons certified by this board it is necessary for a limited time to request a voluntary annual prorata contribution from diplomates after the first year's certification to help defray expenses.

AMERICAN BOARD OF PREVENTIVE MEDICINE

Walter L. Bierring, Chairman, Des Moines, Iowa.
Felix J. Underwood, Vice Chairman in Public Health, Jackson, Miss.
Brig. Gen. Otis O. Benson, Vice Chairman in Aviation Medicine, Washington, D. C.
Gaylord W. Anderson, Minneapolis.
J. H. Baillie, Toronto, Canada.
Richard F. Boyd, Boston.
Leroy E. Burney, Indianapolis.
Matthew R. Kinde, Battle Creek, Mich.
William P. Shepard, San Francisco.
James S. Simmons, Boston.
Jan H. Tillisch, Rochester, Minn.
V. A. Van Volkenburgh, Albany, N. Y.
Reginald M. Atwater, Alternate, New York.
Ernest L. Stebbins, Secretary-Treasurer, 615 North Wolfe Street, Baltimore.
John C. Hume, Assistant Secretary, Baltimore.

CONSULTANTS

Col. Tom Whayne (Army).
Capt. Otto L. Burton (Navy).
Erwin C. Drescher (Public Health Service).
Col. Fratis L. Duff (Air Force).
Katherine Bain (Children's Bureau).
George R. Callender (Veterans Administration).
Basil MacLean, Rochester, N. Y.

ELIGIBILITY REQUIREMENTS FOR EXAMINATION

General Requirements

1. Good moral character and high ethical and professional standing.

2. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association, or from a foreign medical school satisfactory to the board.

3. An internship of at least one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or in a foreign hospital satisfactory to the board.

4. Licensure to practice medicine in the United States or in the Dominion of Canada.

SPECIAL REQUIREMENTS IN PUBLIC HEALTH

1. Successful completion (after internship) of at least one academic year of graduate study leading to the degree of Master of Public Health or an equivalent degree or diploma; or training or study deemed by the board to be substantially equivalent to such graduate study:

2.* Residency (after internship) of at least two years of field experience in general public health practice, which included planned instruction, observation, and active participation in a comprehensive, organized, public health program, one year of which may be an approved clinical residency in a field directly related to public health;

3. A period (after internship) of not less than three years, in addition to 1 and 2 above, of special training in or teaching or practice of public health; and

4. Limitation of practice to full-time teaching or practice of public health as a specialty.

---

* Approval of Residency training is in the process of development. Until such time as an adequate program of residency is developed, field training will be evaluated by the Board on an individual basis. Information as to approved residencies may be obtained from the Council on *Medical Education and Hospitals* or from the Secretary of the Board.

SPECIAL REQUIREMENTS IN AVIATION MEDICINE

1. Successful completion (after internship) of at least two academic years of graduate study in preventive medicine and aviation medicine, one year of which graduate study shall be in a school of public health accredited for the purpose of such graduate study by the American Public Health Association and one year of which shall be in a school of aviation medicine accredited for the purpose of such graduate study by the Council on Medical Education and Hospitals of the American Medical Association; or training and study deemed by the board to be substantially equivalent to such graduate study;

2. * Residency (after internship) of at least two years of supervised experience in aviation medical practice, which included planned instruction, observation, and active participation in a comprehensive, organized program of aviation medicine, one year of which may be an approved clinical residency in a field directly related to aviation medicine.

3. A period (after internship) of not less than two years, in addition to 1 and 2 above, of special training in or teaching or practice of aviation medicine;

4. Limitation of practice to full-time teaching, research or practice of aviation medicine; and

5. Regular and frequent participation in aerial flight.

Credit for training and experience in public health or aviation medicine while in military service will be considered on an individual basis, depending on the type of service.

APPLICATIONS

Each application for examination must be made on the prescribed form (which may be obtained from the secretary) and be accompanied by the required documentation, and must be filed with the secretary, ordinarily not less than 90 days prior to the date of the examination. The application must be accompanied by an application fee and two recent, clear, unmounted, autographed photographs of the applicant, one of which should be attached to the application and the other unattached.

FEES

The fee for application and examination is $90, payable as indicated below; additional fees are payable for reexamination, as set forth below, but no additional fee is payable for the issuance of a certificate.

Application fee, $15. No application will be considered unless accompanied by the application fee. The application fee is not refundable.

Examination fee, $75. This fee is payable when the candidate is notified of acceptance for examination, and, if paid prior thereto, is not refundable after such notification has been given.

No member of the board is authorized to give informal opinions as to the eligibility of the candidates. The determination of eligibility will be made only by the board after receiving full application information. Each candidate must comply with board regulations in effect at the time the examination is taken, and also those in effect at the time the certificate (if any) is issued, regardless of when the original application was filed. An applicant declared ineligible for admission to examination may refile or reopen his application on the basis of new or additional information within two years of the filing date of his original application without payment of an additional application fee.

Applicants who are declared eligible for examination but who fail to submit to examination within three years of the date of the filing of the application are required to file a new application and to pay a new application fee.

CERTIFICATION IN AVIATION MEDICINE WITHOUT EXAMINATION (THE FOUNDERS GROUP)

The bylaws authorize the board, for a limited period of time, to excuse from examination specialists in aviation medicine who have attained high academic rank or have had a minimum of ten years of distinguished service in the field of aviation medicine and are considered eligible by the board, whether or not they meet the eligibility requirements previously referred to. Applications for consideration as members of the Founders Group must be received not later than July 1, 1954. The application fee must accompany the application, and the examination fee is payable before certification even though the applicant be excused from examination.

EXAMINATIONS

Examinations will be held from time to time and in various places depending on need as indicated by applications received. It is expected that examinations will be held primarily in connection with the meetings of the American Public Health Association. For the convenience of military personnel assigned overseas the board will try to provide for special individual examinations at times when such officers are temporarily returned to the United States. The examination consists of two parts:

Part one is a comprehensive written examination designed to test the knowledge of the applicant in the general field of preventive medicine and public health.

Part two is an oral or practical examination which will usually be held on the day following the written examination. An endeavor will be made to adapt the details of the oral examination to each candidate's experience and practice. The examiners will report on each candidate to the assembled board, by which the results of the examination will be considered.

REEXAMINATION

Candidates failing the first examination taken may, upon timely request, be admitted to a second examination within 18 months following the examination failed, upon payment of an additional fee of $15. If the candidate fails the second examination, a period of eleven months must elapse before admission to a third examination. A fee of $25 is required for admission to the third examination. Candidates failing three examinations will not be admitted to any subsequent examinations unless the board so directs.

CERTIFICATION

On satisfactory completion of the examination and proof to the satisfaction of the board that the applicant is eligible for certification, a certificate will be issued to the effect that the person named has been found to be possessed of special knowledge in the field specified in his application. The certificate will be signed by the officers of the board and will have its seal affixed. Each certificate remains the property of the board, but the person to whom it is issued shall be entitled to its possession unless and until it is revoked. Any certificate issued by the board may be revoked if evidence, satisfactory to the board, is presented that the applicant was not eligible to receive it at the time of examination or issuance, or that he misstated, misrepresented, or concealed any pertinent fact, or that his license to practice medicine has been suspended or revoked, or that he has ceased to be engaged in the teaching or practice of the specialty in which he has been certified. The issuance of a certificate to any person does not constitute such a person a member of the board.

AMERICAN BOARD OF PROCTOLOGY

Walter A. Fansler, President, Minneapolis.
George H. Thiele, Vice President, Kansas City, Mo.
Garnet W. Ault, Washington, D. C.
Harry E. Bacon, Philadelphia.
A. W. Martin Marino, Brooklyn.
Louis E. Moon, Omaha.
Hyrum R. Reichman, Salt Lake City.
Robert J. Rowe, Dallas.
R. A. Scarborough, San Francisco.
Louis A. Buie, Secretary, 102-110 Second Ave., S.W., Rochester, Minn.

Associate Members

J. Edwin Alford, Buffalo.
R. J. Jackman, Rochester, Minn.
Jack Kerr, Dallas.
Stuart T. Ross, Hempstead, N. Y.

Advisory Council

Curtiss Rosser, Dallas.
Louis J. Hirschman, Traverse City, Mich.

TYPES OF CERTIFICATION

An application for certification is a voluntary act. Two types of certification will be offered until Jan. 1, 1955. Certificates will be issued (1) to those who fulfil requirements for certification as specialists in the diagnosis and treatment of anorectal diseases exclusive of those conditions which require surgical operation within the abdomen and those which require radical operation for malignant disease of the rectum, and (2) to those who fulfil requirements for certification as specialists in the diagnosis and treatment of anorectal and colonic diseases. The essential difference between the two types of certification is that diplomates of the first type will not be certified to administer treatment which requires surgical operation within the abdominal cavity nor to perform radical operations for malignant disease of the rectum, while diplomates of the second type will be certified to administer such treatment and perform such operations. After Dec. 31, 1954, the first type of certification will be discontinued.

QUALIFICATIONS OF CANDIDATES

This board does not intend to interfere with any practitioner of medicine in his legitimate activities but wishes only to certify, in so far as possible, to the public that physicians who claim to be specialists in anorectal surgery and proctology possess proper qualifications. Suitable evidence of such qualifications can be obtained only if a physician can satisfy this board concerning his training and can thereafter pass examinations required for certification.

GENERAL REQUIREMENTS

All candidates shall comply with the current regulations of the board regardless of the time of filing applications. The secretary is not permitted to make decisions pertaining to requirements. Such decisions are made by the special committees or by the board upon review of the candidate's formal application.

All candidates shall have limited their practice to proctology and/or anorectal surgery.

All candidates shall appear personally before the board.

All candidates shall submit to the required examinations.

A candidate may be requested to deliver to the board a record of all of his patients hospitalized during the year prior to the date of submission of the application. Each record shall be endorsed by an appropriate official of the hospital and must include the diagnosis, treatment, outcome, and dates of admission and discharge from the hospital.

Candidates shall submit a bibliography of papers and books published.

Candidates shall possess the following qualifications:

1. High ethical and professional standing.
2. Authorization to practice medicine in the county, state, territory, or province of his residence.
3. Membership in the American Medical Association or the corresponding recognized medical association of the country in which he resides.

Specific requirements for applicants who desire certification in Proctology:

1. One year of internship in a hospital acceptable to the Council on Medical Education and Hospitals of the American Medical Association following completion of a four year course in a class A medical school.
2. Four years of graduate training, after internship, in medical institutions approved by the Council on Medical Education and Hospitals of the American Medical Association and recognized by the American Board of Proctology. This shall include graduate training in the basic sciences according to the standards prescribed by the Council on Medical Education and Hospitals of the American Medical Association and recognized by the American Board of Proctology. Of the four years of graduate training prior to examination for certification in proctology, two years shall be spent in an approved residency in proctology. When the majority of cases in the approved general surgical residency is in the field of abdominal surgery, three years of an approved general surgical residency and one year of an approved residency in proctology may be accepted.
3. In individual instances credit may be granted for training in proctology obtained in preceptorships approved by the American Board of Proctology.

FEES

1. Application fee. A fee of $25.00 shall be due and payable when the application blank is submitted by the candidate to the secretary.
2. Examination fee for anorectal surgery. A fee of $100.00 shall be due and payable when the candidate is notified that his application has been approved.
3. Examination fee for proctology. A fee of $150.00 shall be due and payable when the candidate is notified that his application has been approved.
4. A fee of $50.00 for a second reexamination in either Part I or Part II shall be due and payable when the candidate is notified that his application has been approved.
5. No fees shall be returnable to the candidate without approval by the board.
6. Each diplomate shall be required to pay a fee of $10.00 annually to the board for a period of 10 years following certification.

APPLICATION FOR CERTIFICATION

Each application for certification shall be filed with the secretary upon the prescribed form which shall bear the endorsement of two proctologists who may be consulted for information regarding the applicant. The endorsers shall be qualified proctologists but shall not be members of the board.

The application shall be accompanied by two unmounted autographed recent photographs of the applicant.

The application should be accompanied by letters of endorsement from appropriate sources.

EXAMINATIONS

Examinations shall be conducted at such times and places as announced in The Journal.

Part I in anorectal surgery and proctology shall consist of written examinations in the subjects of anatomy, physiology, pathology, bacteriology, biochemistry, and other basic sciences considered appropriate by the board.

Part II shall consist of written and oral examinations covering the theory and practice of Anorectal Surgery or Proctology. This examination will include roentgenologic interpretation and other subjects considered appropriate by the board.

A board member or designated examiner will conduct an examination of the applicant in his own community. This examination will involve the following procedures: 1. Surgical operations. 2. Hospital rounds. 3. Inspection of office and hospital records. 4. Conduct of office practice.

GRADES AND REEXAMINATIONS

An average of 75% is the minimum grade that will be acceptable for certification of a candidate.

If a candidate shall fail in Part I he will be required to wait one year before he may be reexamined.

If a candidate shall pass Part I and fail Part II he will be required to wait one year before he may be reexamined.

If a candidate shall fail the reexamination in Part I or Part II, he may petition the board for another examination. With such a petition, the candidate shall submit acceptable evidence of further preparation. Approval or denial of another reexamination shall be determined by the board.

CERTIFICATES

The certificate shall be in a form approved by the board. It shall be signed by the president or vice president and by the secretary, and sealed with the corporate seal.

The certificate in proctology shall indicate that the candidate has been found qualified to practice proctology.

The certificate in anorectal surgery shall indicate that the candidate has been found qualified to practice anorectal surgery.

The cost of both certificates shall be assumed by the board.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

Roland P. Mackay, President, Chicago.
George N. Raines, Vice President, Washington, D. C.
Bernard J. Alpers, Philadelphia.
Kenneth E. Appel, Philadelphia.
Russell N. DeJong, Ann Arbor, Mich.
Francis M. Forster, Washington, D. C.
Francis J. Gerty, Chicago.
William Malamud, Boston.
Frederick P. Moersch, Rochester, Minn.
George H. Stevenson, London, Ontario, Can.
Paul I. Yakovlev, Boston.
David A. Boyd Jr., Secretary-Treasurer, 102-110 Second Ave., S.W., Rochester, Minn.

APPLICATION FOR CERTIFICATES

An application, in order to be considered at any meeting of the board, must be in the hands of the secretary of the board not less than 90 days before the date of such meeting. A proper application form may be obtained from the secretary. Application may be made for certification in psychiatry or in neurology or in both fields. Applications will be formally considered only when made on the official application blank in such form as may be adopted from time to time by the board and when accompanied by an application fee in such amount as may be fixed by the board.

The secretary of the board, on receipt of an application, shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the Committee on Credentials. This committee shall consider the application and other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire board at any meeting held for such certification.

FORM OF CERTIFICATION

There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certifications shall be in such form as is approved by the Board of Directors.

GENERAL REQUIREMENTS FOR APPLICANTS

Each applicant for a certificate must establish that:

(*a*) He is a physician duly licensed by law to practice medicine.

(*b*) He is of acceptable ethical and professional standing.

(*c*) He is now a member of the American Medical Association or a member of such medical societies as are recognized for purposes of certification by the Council on Medical Education and Hospitals of the American Medical Association. Exceptions to the foregoing may be made at the discretion of the board for good and sufficient reasons.

(*d*) He has received adequate training in psychiatry or neurology, or both, as a specialty.

CLASSES OF APPLICANTS

Class A.—Applicants who graduated from an approved medical school before the foundation of the board (1934) will not be held to the strict interpretation of the published requirements in formal graduate training. Under such circumstances the board will consider the training and experience of the applicant and decide whether or not he will be admitted to the examinations. After Jan. 1, 1954, for such graduates the board will consider 10 years of full-time acceptable experience in psychiatry or neurology in lieu of the formal training requirements. Should the candidate then apply for supplementary certification, the Credentials Committee will require five years of additional acceptable experience in the supplementary field.

Class B.—Applicants who graduated from an approved medical school after 1934 shall fulfil the following requirements.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose medical training has been received outside the United States and Canada, such training must be satisfactory to the aforementioned Council.

2. Completion of a year's internship approved by the same Council in general medicine, general surgery, pediatrics or a rotating service.

3. The nine month wartime internships will be accepted as an equivalent of one year.

SPECIALIZED TRAINING

Admission to the examination for certification in psychiatry or in neurology requires a total of five calendar years of training and experience, three years of which must be specialized training obtained in approved training centers, plus two years of experience. Admission to the examination for certification in both psychiatry and neurology requires a total of six calendar years of training and experience, five years of which must be specialized training obtained in approved training centers, plus one year of experience. The specialized training may be subdivided into two and one-half years each in psychiatry and neurology or three years in one subject and two years in the other. The required years of experience should be spent in clinical practice with major responsibility for the care of patients.

This training for psychiatrists should include clinical work with psychoneurotic and psychotic patients, combined with the study of basic psychiatric sciences, medical and social psychology, psychopathology, psychotherapy and the physiological therapies, including a basic knowledge of the form, function and pertinent pathology of the nervous system. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training period should include instruction in the psychiatric aspects of general medical and surgical conditions and the behavior disorders of children and adolescents sufficient to develop practical ability to direct the treatment of such conditions. It should also include collaborative work with social workers, clinical psychologists, courts and other social agencies. The training program of the candidate for certification in psychiatry should include sufficient training in neurology to enable him to recognize and to evaluate the evidences of organic neurological disease.

The training for neurologists should be based on clinical work with adults and children with neurological disorders, including the neurological complications of medical and surgical conditions. This should be combined with study of basic neurological sciences, neuroanatomy, neurophysiology, neuropathology and neuroroentgenology. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training should include sufficient training in psychiatry to enable the candidate to recognize and to evaluate the common psychiatric reactions.

The board offers the foregoing two paragraphs as an outline of desirable training. If, however, the candidate has evidence of equivalent qualifications of training and experience not in the pattern here formulated, this evidence with appropriate documentary support may be included in his application for evaluation and possible approval by the board.

Candidates seeking certification in both neurology and psychiatry or supplementary certification in one after being certified in the other must submit evidence satisfactory to the board of an additional two years of full time basic training in the supplementary specialty.

Thus, no candidate is eligible for examination by the board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least six years of special training and experience in neurology and psychiatry for certification in both neurology and psychiatry.

The board will give not more than six months of credit for not less than six months of training in an approved training center for internal medicine or pediatrics in lieu of six months of experience to candidates for the certificate in psychiatry or neurology, but not to candidates for certification in both psychiatry and neurology.

The board will give credit for one year of training in child psychiatry providing it is the third year of the required three years of special training required by the board and providing it is taken in a center approved by this board for training in child psychiatry. After July 1, 1956, training credit for work in the field of child psychiatry may be gained only by participation in a hospital residency training program that is regularly approved. After that date, all independent training approval of psychiatric clinics for children is discontinued.

The list of training programs approved by this board and by the Council on Medical Education and Hospitals of the American Medical Association may be found in the current issue of the Internship and Residency number of The Journal.

The secretary may at his discretion admit to examination candidates who lack not more than two months of the time requirement for certification with the understanding that the certificate will in no case be issued until satisfactory written evidence of completion of this requirement is submitted to the board.

TRAINING IN THE ARMED FORCES

Credit will be granted for one year of wartime military service in the Army, Navy, Public Health Service and Veterans Administration. Wartime to this board means Dec. 7, 1941 to Feb. 15, 1946. Further credit for specialized training will be granted only if the candidate has received training in an institution recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by this board. Time beyond one year spent in the above government agencies may be credited to experience providing the candidate has been regularly assigned to a service in neurology or psychiatry.

Training and experience credit toward requirements for examination will be granted for military duty in present emergency under certain conditions. This policy relates to active military medical duty since July 1, 1950. One year of training credit will be granted for one year spent in full-time psychiatric and/or neurological duties. Additional training credit will be granted for that amount of time spent in approved training programs. Experience credit will be granted for any remaining time spent in full-time psychiatric and/or neurological assignments. Double credit will not be granted for any single period of time.

EXAMINATIONS

Dates and places of examinations are set by the board at its discretion and shall be announced in The Journal, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Diseases*, and in the *Archives of Neurology and Psychiatry*.

Though the purpose of the examination is to test the competence of the candidate in psychiatry or neurology or both, it must not be forgotten that both these medical disciplines constitute part of the broad field of general medicine. The board requires some proficiency in neurology on the part of those it certifies in psychiatry, and vice versa, but examines the candidate in accordance with the certificate he seeks. The examinations will be of such type that no adequately trained person will fail and yet they will be sufficiently searching so that the specialist in fact may be separated from the specialist in name. The practical examination will include the examination of patients under the supervision of the examiner. The manner of examining patients, and the reasoning and deductions therefrom, will constitute an important part of the examination. Oral and practical examinations will be given in the basic sciences with special regard to their clinical implications. Written examinations may be given at the discretion of the board. The examination for certification in psychiatry will differ from the examination for certification in neurology.

PAYMENT OF FEES

The candidate on filing his application shall accompany it with an application fee of $35 which is not returnable. If a preliminary written examination has been decreed, an additional $25 fee will be required at the time of the applicant's acceptance. When notified by the secretary that he is eligible for the oral and practical examination, the candidate shall send to the secretary an examination fee of $65. A candidate who has been certified in either psychiatry or neurology and who has been admitted to supplementary examination for the other certificate shall pay an additional examination fee of $65.

A candidate who has failed in one examination is eligible for reexamination within one year on payment of a reexamination fee of $50. After the year has elapsed he must submit a new application and pay new application and examination fees. If he fails the reexamination, he may, after two years have elapsed, submit a new application and $35 fee, present evidence of further training and pay an examination fee of $65.

A candidate who fails in one or two subjects is eligible for reexamination in those subjects within one year on payment of a reexamination fee of $50. After the year has elapsed he must submit a new application and pay new application and examination fees and repeat the entire examination. If he fails the reexamination, he may apply again for the complete examination after two years on submission of evidence of further training and on payment of an application fee of $35. If admitted to the examination, he must pay a new examination fee of $65.

Any candidate who finds himself unable to attend an examination to which he has been admitted and does not notify the secretary at least six weeks before the date of the examination will forfeit half of his examination fee. Any candidate who fails to appear for examination within a period of three years following the date of notification of eligibility for examination shall be required to submit a new application and pay the attendant fee. If a candidate dies before his certificate is issued, all fees will be returned to his estate.

AMERICAN BOARD OF RADIOLOGY

Douglas Quick, President, New York.
H. Dabney Kerr, Vice President, Iowa City.
Ralph S. Bromer, Bryn Mawr, Pa.
John D. Camp, Los Angeles.
D. S. Childs, Syracuse, N. Y.
A. H. Dowdy, Los Angeles.
Ross Golden, New York.
E. L. Jenkinson, Chicago.
I. H. Lockwood, Kansas City, Mo.
F. W. O'Brien, Boston.
J. W. Pierson, Baltimore.
U. V. Portmann, Cleveland.
Leo G. Rigler, Minneapolis.
B. P. Widmann, Philadelphia.
B. R. Kirklin, Secretary-Treasurer, 102-110 Second Avenue, S.W., Rochester, Minn.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges or license to practice radiology. Certificates of the board shall be issued on one of four forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all of its branches.

2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (*a*) roentgenology; (*b*) diagnostic roentgenology; (*c*) therapeutic radiology.

3. A certificate to the effect that the applicant has been found qualified to practice radiological physics in all of its branches.

4. A certificate to the effect that the applicant has been found qualified to practice radiological physics in one or more of the following special fields: (*a*) x-ray and radium physics; (*b*) medical nuclear physics.

DEFINITIONS

For the purposes of this board, the following definitions are adopted:

1. Radiology is that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.

2. Roentgenology is that branch of radiology which deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology which deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology which deals with the therapeutic application of roentgen rays, radium and radioactive isotopes.

5. Radiological physics is that branch of physics which deals with the medical application of roentgen rays and the radiations from radioisotopes, nuclear reactions and particle accelerators.

6. X-ray and radium physics is that branch of radiological physics which deals with roentgen rays and radium.

7. Medical nuclear physics is that branch of radiological physics which deals with radioisotopes, nuclear reactions and particle accelerators.

GENERAL REQUIREMENTS

Each applicant for admission to the examination for a certificate in radiology shall be required to present evidence that he has met the following standards:

GENERAL QUALIFICATIONS

1. Satisfactory moral and ethical standing in the profession.

2. A license to practice medicine in the state or county in which he resides.

3. Membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as herein provided, membership in other societies shall not be required.

4. That the applicant holds himself out to be a specialist in radiology or one of its branches as defined under "definitions," and that he devotes his time primarily and principally (at least 75 per cent) to the practice of radiology or one of its branches.

5. That he is a citizen of the United States or Canada. Candidates from other countries must be permanent residents of that country and native citizens thereof.

GENERAL PROFESSIONAL EDUCATION

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

1. After completion of the internship there shall be a period of special training in radiology of not less than three years in clinics, hospitals or dispensaries recognized and approved by the American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in radiology. This period of specialized training shall include:

(*a*) Graduate training in pathology, radiation physics and radiobiology. A period of six months full-time training in pathologic anatomy is recommended but where this is not possible to arrange, the student during his three-year training period, may, by attending pathologic conferences, postmortem examinations and studying removed tissues, receive adequate training in pathology. It is recommended that radiation physics be taught by a combination of didactic lectures, practical examples and direct clinical demonstrations.

(*b*) An active experience (residency) of not less than twenty-four months in an institution, the radiologic department of which is recognized and approved by the American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as capable of providing satisfactory training.

(*c*) Examination in the basic sciences of radiology as well as the clinical aspects thereof. These examinations should be given by the student's instructors in order to allow those responsible for his training to certify to the board that he is adequately prepared.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical and radiologic), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiologic literature, his membership in medical societies and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs and the fee of $75 at least three months before the date of the examination.

FEE

A fee of $75 must accompany each application blank. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board and special examiners do not receive any compensation except for actual expenses connected with holding the examinations. As the number of candidates decreases, it may become necessary to raise the fee.

EXAMINATIONS

Each year the board will hold an examination in conjunction with the annual meeting of the American Medical Association, and, when sufficient applications are on file, a second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society and/or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics and radiobiology, as well as the clinical application of roentgen rays, radium and radioactive isotopes. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiencies.

REEXAMINATIONS

If the candidate fails in the first examination he will be admitted to a second examination after one year has elapsed but not more than three years. He must give 90 days' notice of his intention to appear for reexamination and pay an additional fee of $35. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of $75.

A candidate having failed twice may, after one year has elapsed, file a new application which must be accompanied by the fee of $75.

AMERICAN BOARD OF SURGERY

Thomas H. Lanman, Chairman, Boston.
John H. Mulholland, Vice-Chairman, New York.
William A. Altemeier, Cincinnati.
Lawrence Chaffin, Los Angeles.
Clarence E. Gardner, Jr., Durham, N. C.
John H. Gibbon, Jr., Philadelphia.
Frank Glenn, New York.
Peter Heinbecker, St. Louis.
Gustaf E. Lindskog, New Haven, Conn.
William K. Livingston, Portland, Oregon.
Walter G. Maddock, Chicago.
Leland S. McKittrick, Boston.
James D. Rives, New Orleans.
John D. Stewart, Buffalo, N. Y.
John M. Waugh, Rochester, Minn.
John B. Flick, Secretary and Treasurer, 225 S. Fifteenth Street, Philadelphia, 2.
Cletus W. Schwegman, Assistant to the Secretary, Philadelphia.

REQUIREMENTS

GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession and in the community must be satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to a traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Certification is restricted to those whose activities are limited to the practice of surgery, including diagnosis, preoperative and postoperative care.

PRELIMINARY TRAINING

1. Graduation from a medical school of the United States or Canada accredited by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered acceptable to the board.

2. Completion of an internship (straight, mixed or rotating) of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board, such as a year of study devoted to a single branch of medicine.

SPECIAL TRAINING

INTRODUCTION

It is not and never has been the policy of the American Board of Surgery to require that a candidate perform a specific number of operations before taking its examination. The only two components of a residency which can be measured are the number of operations performed and the duration of the training period; the more significant and intangible factors are difficult to evaluate. These include:

1. The professional competence and the integrity of the senior staff and their ability and willingness to teach.
2. The responsibility given the resident.
3. The attitude of inquiry pervading the service.
4. The opportunity afforded the resident for study, investigation and teaching.

Adequate operative experience is concerned more with the variety and magnitude of operations performed than with actual numbers. In certain instances the board may require a special operative inspection.

The board interprets the term "general surgery" in a comprehensive manner and expects candidates to have knowledge of the basic principles applied in the treatment of fractures, trauma and head injuries. Knowledge of the more common procedures in plastic, gynecologic, orthopedic and urologic surgery is expected. Some elasticity of the program will be allowed to permit individuals with preferences for work in specialized fields, experimental surgery or research. In such a program the integration of basic sciences, particularly pathology, with clinical training and material is superior to formal courses.

The most important single factor in the development of a surgeon is the opportunity under guidance and supervision to grow by progressive and succeeding assignments to the stature of complete responsibility.

GROUPS I AND II

The requirements of the board to become eligible for its examinations may be fulfilled by either of the two programs outlined below. Both of these educational programs are considered by the board to be minimal in attaining its purposes.

Group I—A candidate must have completed a four-year graded residency or clinical fellowship in surgery in an institution or institutions acceptable to the board and conference committee. Three of the four years must be spent in general surgery. One of the four years may be spent in any manner which an acceptable program provides.

Group II—As yet there is not a sufficient number of hospitals capable of offering a four-year graded residency in surgery. The board, therefore, will continue to recognize three years of approved residency or fellowship training in a hospital approved by the conference committee. The two additional years over and above this to complete a total of five may be spent in practice limited to surgery carried out under acceptable supervision. One of these two years may be spent in the study of the basic sciences in a fully approved graduate school of medicine.

NOTE:—In both Group I and Group II, the supervising surgeon must vouch for the candidate's integrity, surgical judgment and technical skill. Sufficient operative work performed independently under supervision to fortify residency training must be attested to by a statement submitted to the board at the time the candidate makes application.

BASIC SCIENCES

The board does not insist that any special length of time be spent in the basic sciences, but knowledge of these sciences as applied to clinical surgery will be required in the examinations. The board will grant credit for postgraduate work in basic sciences (full time) provided that such study extends over a period of not less than six months.

MILITARY CREDIT

If a candidate has served in a government hospital or hospitals fully approved for residency training, such training will be acceptable to the board. Military credit may be extended to those candidates who have served in non-approved hospitals provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical material and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the board. Any credit extended in the latter category will be considered preceptorship credit and not residency credit.

REQUIREMENTS FOR FOREIGN BORN AND FOREIGN TRAINED APPLICANTS

Full citizenship status is required of residents of the United States. United States citizens who are residents of other countries, and citizens of other countries must have completed at least the three year residency training requirements in a hospital in the United States or Canada. In addition, they are required to hold a license to practice surgery in the country in which they hold citizenship. The Examination Committee may, in individual instances, accept foreign training as the equivalent of acceptable residency training in the United States.

APPLICATIONS

Prospective candidates for examination by the board should carefully read the board's requirements as set forth in its Booklet of Information. If, after becoming familiar with the board's requirements, the candidate needs advice as to his training, such may be had by writing to the board's office. When a candidate's training seems to meet the board's requirements, an application blank will be mailed. The processing of the completed application requires a minimum of three months by the board's office. The candidate will then be notified by the secretary as to his acceptability for examination, his deferment or his ineligibility.

The eligibility of candidates whose training in some respects does not conform to requirements published above will require the action of the Examination Committee of the board which may postpone the candidate's notification of acceptability. Every candidate's final acceptability for examination is based not only on the evaluation of his training qualifications, but on recommendation by the board's advisors as to his professional ability as a surgeon, his ethical standing in the community, and the strict limitation of his work to surgery.

THE FOUNDERS GROUP

The Founders Group, to which were admitted those who had already amply demonstrated their fitness as trained specialists in surgery, was closed in January, 1940.

EXAMINATIONS

The qualifying examination will be divided into Part I (written) and Part II (clinical, bedside and laboratory). In both of these parts, as previously stated, a knowledge of the practical application of the sciences fundamental to surgery will be required.

Part I

This examination will be given simultaneously in as many centers throughout the country as the board may determine suitable for the purpose, and is held twice a year—in the spring and fall. All applications must be on file in the board's office at least three months in advance of the examination. Candidates who are declared eligible are given ample notice as to the center to which they have been assigned for examination.

The examination in Part I is written and covers a one day period. There shall be two sessions of three hours each. The examination concerns itself primarily with general surgical problems including the application of the basic sciences of surgery to these problems.

Part II

The board may, at its discretion, require that a satisfactory operative report be filed before a candidate is eligible for Part II. Such a report shall be made by a member of the board, Founders Group, or one certified by examination, designated to be present during a major operative procedure performed by the candidate.

Part II of the examination shall be oral and practical and cover a one day period, the schedule being arranged somewhat as follows:

8:15 A. M.—Registration.

9 A. M. to 1 P. M.—Clinical surgery (diagnosis, management and the application of physiology, biochemistry and bacteriology, as the case being examined upon may offer an opportunity for doing so. Roentgenographic interpretation will also be included).

2 to 5 P. M.—Applied Anatomy and Surgical Pathology.

The board expects that every candidate shall be well prepared in applied anatomy and in surgical pathology. In the latter subject more stress is laid on an understanding of disease processes and their clinical implications than on the recognition of gross and microscopic lesions.

Examinations in Part II are conducted in certain centers of the country selected by the board. It is the board's desire to arrange these centers so as to geographically meet the needs of the candidates, on condition that suitable examination facilities can be provided. Examinations in Part II are conducted by members of the board together with selected diplomates of the board.

GRADES

A candidate must receive an average of 75 per cent for each part to be entitled to the board's certificate.

REEXAMINATIONS

Part I. Candidates who fail Part I are required to wait one year before becoming eligible for reexamination.

Part II. Candidates who fail Part II in its entirety and those who fail in the single subject of clinical surgery are required to wait one year before establishing eligibility for reexamination. Those who fail either anatomy or pathology are required to wait six months. The board expects that during this period the candidate will make a reasonable effort to prepare himself in the subject or subjects in which he has failed.

Should a candidate fail a reexamination in Part I or Part II, further examination privileges will be denied. Appeal for further examination under special circumstances, when satisfactory evidence of further training has been submitted, will be considered by the Examination Committee. The board may, however, for good and sufficient reason, deny a candidate the privilege of further reexamination.

FEES

The fee for the examination is $100, payable as follows: $10 registration fee, $30 for Part I and $60 for Part II.

Candidates shall be required to pay a fee of $30 for reexamination in Part I and $60 for reexamination in Part II.

This board is a nonprofit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses, to aid in improving existing opportunities for the training of the surgeon. *The members of the board serve without remuneration.*

CERTIFICATE

After meeting the requirements for eligibility and passing the examinations, a certificate attesting to a candidate's qualifications in surgery will be issued by the board, signed by its officers.

The board has discharged its responsibilities by conducting examinations and has issued certificates of qualification to those surgeons who have met certain clearly specified educational requirements and have successfully passed its examinations. In discharging its responsibilities, the primary purpose of the board has been to establish and maintain desirable standards in the education and training of the young surgeon.

The American Board of Surgery has never been concerned with measures that might gain special privileges or recognition for its diplomates in the practice of surgery. *It is neither the intent nor has it been the purpose of the board to define requirements for membership on the staffs of hospitals.* The prime object of the board is to pass judgment on the education and training of broadly competent and responsible surgeons, not who shall or shall not perform surgical operations. The board specifically disclaims interest in or recognition of differential emoluments that may be based on certification.

BOARD OF THORACIC SURGERY

(An Affiliate of the American Board of Surgery)

Cameron Haight, Chairman, Ann Arbor, Mich.
Richard H. Sweet, Vice Chairman, Boston.
William E. Adams, Chicago.
Frank E. Berry, New York.
Brian B. Blades, Washington, D. C.
Thomas H. Burford, St. Louis.
Michael E. DeBakey, Houston, Texas.
George H. Humphreys, New York.
Julian Johnson, Philadelphia.
John C. Jones, Los Angeles.
William M. Tuttle, Secretary-Treasurer, 1151 Taylor Avenue, Detroit 2, Mich.

FUNCTIONS OF THE BOARD

1. To Select Founder Members. For this group surgeons of the United States and Canada were chosen who had made meritorious contributions to thoracic surgery.

The Founders Group was kept open for two years after organization of the board.

It was officially closed April 14, 1951.

2. To conduct examinations of satisfactory candidates who seek certification by the board.

3. To improve the opportunities for the training of thoracic surgeons.

4. To set up principles of education to guide young surgeons who desire to prepare themselves for proficiency in thoracic surgery.

5. To issue certificates of qualification to all those meeting the board's requirements.

REQUIREMENTS

1. Certification by the American Board of Surgery.

2. Two years' training in thoracic surgery approved by the Board of Thoracic Surgery, or meritorious contributions to thoracic surgery. One of these two years may be spent during the four years of training in surgery required by the American Board of Surgery.

3. Written, oral and practical examination.

DEFINITION OF WHAT IS CONSIDERED ACCEPTABLE TRAINING IN THORACIC SURGERY

To qualify for the examination in thoracic surgery, the candidate shall have had two years of training in an active, well-integrated thoracic surgical clinic or clinics, or the equivalent amount of thoracic surgical training, on a mixed service consisting of thoracic and nonthoracic surgical cases. Adequate training in both the tuberculous and nontuberculous aspects of thoracic surgery is expected. In order to obtain this objective, combined residencies between institutions of different types may be advantageous. It is also required that the candidate be familiar with the basic sciences as related to thoracic surgery. Under exceptional circumstances certain surgeons may, by virtue of recognized proficiency in the surgical treatment of thoracic diseases, qualify for the examination at the discretion of the board.

APPLICATIONS

Prospective candidates desiring to apply for examination should consider whether they are able to meet the minimum requirements of the board. They should then submit a letter to the secretary's office, outlining briefly their training and experience in thoracic surgery and ask for an application form. An application form will not be sent unless evidence is submitted in a letter indicating that the prospective applicant appears to meet the minimum requirements.

EXAMINATIONS

The Board of Thoracic Surgery will be governed in general by the rules laid down by the American Board of Surgery pertaining to examination, as well as reexaminations.

Rules may be changed, however, at the discretion of the Board of Thoracic Surgery.

FEES

For the special examination in thoracic surgery and the issuing of a certificate, the fee will be $100. Fifteen dollars of this fee is to accompany the application and will be considered as a registration fee. It is nonreturnable to the applicant in case he is disapproved for examination.

The fee for reexamination will be $25.

AMERICAN BOARD OF UROLOGY

George F. Cahill, President, New York.
Edgar Burns, Vice President, New Orleans.
Grayson Carroll, St. Louis, Mo.
A. I. Dodson, Richmond, Va.
Rubin Flocks, Iowa City.
Thomas D. Moore, Memphis, Tenn.
Gilbert J. Thomas, Santa Monica, Calif.
William N. Wishard, Indianapolis.
Harry Culver, Secretary-Treasurer, Chicago.
Mrs. Ruby L. Griggs, Assistant Secretary, Minneapolis.
Office of the Secretary-Treasurer: 30 Westwood Road, Minneapolis 16.

EMERITUS MEMBERS

Clarence G. Bandler, New York.
William F. Braasch, Rochester, Minn.
T. Leon Howard, Denver.
Herman L. Kretschmer, Chicago.
George Gilbert Smith, Brookline, Mass.

APPLICATION BLANK; REQUIREMENTS FOR ALL APPLICANTS

Application for certification must be made on a special form. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials, and by $50 of the examination fee.

Requirements for Applicants.—Each applicant, before he shall become eligible to take the examination for certification in urology, must:

A. Have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association and must have completed an internship of not less than one year in a hospital approved by the same council. (The former requirement is not applicable to a candidate who graduated from an institution now extinct, or whose graduation occurred before the American Medical Association had prepared a list of accredited medical schools.) All graduates of foreign medical schools must obtain a license to practice in the state or province in which they reside, the certificate of the National Board of Medical Examiners and/or the certificate of graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association as capable of providing training comparable with that recognized in a "Class A" medical school.

B. Establish in a manner satisfactory to this board that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing, and that he has received adequate special training in urology.

The board is attempting to increase and to standardize the facilities for urological training in teaching institutions, so that the expression "special training in urology" may be interpreted to include:

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of urology.

The training requirements after the internship may be fulfilled in one of the following ways:

(*a*) A three-year residency in urology.

When a resident obtains a senior rating or is in his final year of training, he should be in charge of the examination and treatment (surgical or otherwise), of an ample number of patients under the supervision of the senior consultant or attending urologist who must be a certificatee of the American Board of Urology.

(*b*) A second year of rotating internship or a one-year residency, preferably in general surgery, followed by a two year urologic residency, which should have the same status as the last two years of a three year urologic residency.

(*c*) Preceptorship.

This type of training may be accepted, but it is not encouraged.

This, and other variations from training described above, must be supported by evidence that the candidate has had training comparable with one of the two preceding types of residencies.

2. An additional period of not less than two years in the practice of urology in the city from which he makes application.

These special requirements conform with the suggestions made by the Council on Medical Education and Hospitals of the American Medical Association.

After June 30, 1955, training requirements, after the internship, may be fulfilled in one of the following ways:

1. One year general surgery. Three years formal training in urology.

2. Two years of general surgery. Two years formal training in urology.

3. One year of general surgery. One year review of basic sciences or some special research. Two years of formal training in urology.

4. One year general surgery. Two years of formal training in urology. One year of credit for two years in a preceptorship, to be approved by the Credentials Committee and the board.

C. Make application to the American Board of Urology, whose duty it shall be to investigate the applicant's credentials and make a survey of his character.

D. Assure the board that he is engaged in the practice of urology and that he intends to continue to be so engaged.

E. Membership in the American Medical Association or comparable national medical association is recommended.

Any candidate who starts training before June 30, 1955, under the old requirements, may complete the program of the old requirements and thereby become acceptable for examination. No more candidates will be accepted for examination whose training has been entirely on a preceptorship basis started after March 1, 1951.

FEE

The examination fee is $150. (This fee will be increased when the expense of the examinations and other activities of the board demand.) Fifty dollars must accompany the application. If, on investigation, an applicant is found lacking in any of the requirements stated above, he will be notified that he is ineligible for examination. One hundred dollars must be paid when the applicant is accepted as a candidate for certification. Neither fee shall be returnable in any event.

If a candidate fails, he will be permitted a second examination after one year or within three years, without additional fee, but he must give 60 days' notice of his intention to appear for reexamination. After an applicant has failed twice, he must file a new application and pay a second fee.

REQUIREMENTS FOR CERTIFICATION

According to the by-laws of the American Board of Urology, applications received from applicants for certification shall be examined by the Credentials Committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary.

The requirements for certification include: preparation of reports of twenty-five representative (not necessarily consecutive) major urological cases from private cases, which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; oral-clinical examinations, written examinations and personal appearance before the board.

In specific instances, the board may waive any part of these requirements, with the exception of the item of personal appearance.

Each candidate will receive a notice of the time and place of the examinations, and an appointment for his personal appearance before the board.

EXAMINATIONS AND REPORTS OF CASE HISTORIES

The board will hold one examination per year. This may be held in association with the annual meetings of the American Urological Association or the American Medical Association, when this is practicable, or at other times and places that the board may select, or deem expedient.

The written examinations are designed to test the candidate's preparation in, and his knowledge of, the whole field of urology, including the fundamental subjects: pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology. These may be given at the time of the oral-clinical examination, or may be held on certain dates simultaneously in different parts of the country at places convenient for candidates. The examination in pathology will consist of the identification of gross specimens and of sections of tissue observed through the microscope. The examination in anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology will be a test of the candidate's working knowledge of these subjects as they are related to the practice of urology.

The oral-clinical examination will consist of discussions of common urological conditions. The subjects forming the basis of this examination are urography; diseases of the genital organs, including the prostate; diseases of the urinary bladder and diseases of the ureters and kidneys. The examination may deal directly with data found in the reports of case histories that the candidates have submitted. It will ascertain the candidate's familiarity with recent literature, the breadth of his clinical experience and his general qualifications for practice in the specialty of urology.

The professional adaptability of each candidate will be investigated in an attempt to determine his ethical conduct and his attitude toward his patients and fellow practitioners.

The reports of twenty-five major urological cases must be representative cases from private practice. The reports must be typewritten on 8½ by 11 paper and in duplicate, but need not be on any special form.

Complete index lists must accompany the reports. If they are obtained from more than one hospital they must be consecutive and a separate index list of each group should be provided. These lists must state the operator's name at the head of each page, the name of the patient, the hospital and admission number, and the dates of operation. Statements from the superintendents of the hospitals attesting that the candidate was the operator *must be included.* With the twenty-five case reports there must also be an index, in consecutive order, of all major and minor urological surgery done during the last two years of practice. The lists should be filed in the secretary's office for verification purposes.

The data should be placed under proper headings and the arrangement of these should conform to the sequence of events incidental to the patient's admission to the hospital or clinic, the examinations made and treatment prescribed.

Sufficient data should appear in these so that the examiner will know that a proper history was taken and that a thorough examination, including a complete physical survey, was made.

The board requires that all of the essential points of the history and examination, as well as a complete description of the surgical procedure, shall be given. Emphasis should be placed on the following items: preoperative diagnosis, clinical and pathological diagnosis, laboratory data, including cultures of urine and chemical analysis of calculi; summary of postoperative course with special reference to morbidity, clinical findings at time of discharge from the hospital and subsequent follow-up reports.

A final short paragraph *must be prepared* for each case. This must include the candidate's interpretation of the history in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; a critical discussion of the knowledge gained from the proper handling of the case, or from the errors made (if any) in the diagnosis and method of treatment.

Each candidate must assume personal responsibility for the data in his case reports, including autopsy findings and interpretation of urograms.

A candidate must remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his competence as a urologist.

The deadline for the receipt of case histories each year is September 1.

Satisfactory case reports must be submitted before a candidate will be permitted to continue with other parts of his examination. If case reports are pronounced unsatisfactory by more than one examiner, the candidate will be informed of this and requested to prepare others.

LIMITATIONS OF FUNCTIONS OF THE BOARD

The conferring of degrees, "Doctor of Medicine" or "Bachelor of Medicine" remains with the universities, where it belongs. This board makes no attempt to control the practice of urology by license, or legal regulation and in no way interferes with or limits the professional activities of any duly licensed physician.

ANNUAL REPORT ON INTERNSHIPS AND RESIDENCIES

In this issue, the Council on Medical Education and Hospitals presents its 27th Annual Report on Internships and Residencies together with a directory of Council-approved programs. The report includes basic information relating to the field of graduate medical education. According to the report, there are now 1,313 hospitals in the United States and its possessions in which internship or residency programs are being conducted. Last year, there were 24,512 interns and residents on duty in these hospitals, including federal, other governmental, and civilian institutions. The effect in terms of patient care of this large number of physicians serving in these hospitals in a full-time capacity is evident, the report states.

As of Sept. 1, 1952, there were 853 hospitals conducting approved intern programs. They offered a total of 10,548 internships, of which 9,497 (90%) were rotating in type. There were a total of 7,645 interns reported on duty last year. Of these, from 1,300 to 1,400 were estimated to be graduates of foreign medical schools. For two successive years, the number of internship positions reported unfilled has been approximately 3,000. In considering the problem of the intern shortage, the report points out, this figure can be considered more accurate than that obtained by comparing the total number of internships with the annual number of medical school graduates in the United States. The internship occupancy rate for all hospitals remained the same as last year at 72%.

Tabular data presented in the report showed that there are now 1,131 hospitals in which approved training at the residency level is being offered, representing 4,634 programs in 27 specialties and general practice. These hospitals provide appointments for 10,285 first year residents and 22,292 positions at all levels, i. e., first, second, third, and fourth years. Specialties in which a relatively high percentage of positions were filled included thoracic surgery, obstetrics-gynecology, general surgery, ophthalmology, pediatrics, and plastic surgery. Those with low occupancy rates included proctology, allergy, physical medicine, general practice, and pathology. There were 16,867 residency positions filled during the reporting period, representing 76% of the total number available. The report comments on the fact that the percentages of vacancies in internship and residency positions are approximately the same and that the problem of house shortages should be considered in its entirety rather than *in terms of internship or residency vacancies.*

It has been said that the development of the internship and residency program in the United States has been one of the more important contributions that American medicine has made to medical education. If graduate education is to achieve its objectives, it must be continually reevaluated by those concerned with its conduct. The Annual Report provides a body of essential information for such an appraisal that is available from no other source. The Council for its efforts in preparing this report and the medical staffs and hospital administrators who provided the basic data are deserving of commendation. Without this information, an evaluation of the current status of graduate education in the United States would be difficult if not impossible to make. The lists of approved services also are indispensable to many persons, organizations, and agencies interested in graduate education. As the Directory of Approved Internships and Residencies, it has become recognized as an official source of information by many federal and state governmental agencies. The Council makes grateful acknowledgment in the report to the hospitals, American Boards, medical schools, and federal agencies through whose assistance and cooperation the publication of the report and the directory is made possible.

THE INTERN SHORTAGE

The perennial problem of the shortage of interns is again brought sharply into focus in the Annual Report on Internships and Residencies, which points out that for the second successive year about 3,000 internships throughout the United States were vacant. The dilemma presented by the wide disparity between the number of applicants and the number of intern appointments available has been the subject of much discussion and serious study for the past several years. It may be pertinent, therefore, to raise the question as to why a satisfactory solution to the problem has not been found.

There are, quite obviously, only two ways by which the present situation can be resolved, or at least ameliorated. The first involves an increase in the number of available interns, either through an expansion of present enrollments in medical schools in this country or through the appointment of larger numbers of graduates of foreign medical schools. As to the former, enrollments in medical schools are now at an all-time high, with 27,688 students registered for the academic year 1952-1953.[1] Further increases in the number of students graduating can be anticipated as additional four year schools are developed. It is probable, however, that schools now in existence are operating at close to full capacity and that additional students from these schools will be limited.

The report states that it can be estimated that there are 1,300 to 1,400 graduates of foreign medical schools currently serving as interns in hospitals in this country. Whether the number of these graduates can or should be increased is moot. There is the practical problem of integrating persons of diverse educational backgrounds, frequently with language handicaps, into a sound training program. Further, the question of their subsequent eligibility for licensure should be given serious consideration in offering these applicants appointments, after completion of which they may find themselves at a dead end. Again, the possibility of increasing the number of eligible applicants for internship positions by this means has definite limitations.

---

[1] Medical Education in the United States and Canada, report by the Council on Medical Education and Hospitals, J. A. M. A. **153**: 118 (Sept. 12) 1953.

The second approach to the problem, then, involves a reduction in the number of internships. One method of achieving this end lies in extending the length of internships to two years rather than the present 12 months currently required in the majority of approved hospitals. It is evident that, were programs of 24 months' duration adopted by all hospitals, the annual requirement for interns would be halved. It is unlikely, however, that such a course could be adopted on a nation-wide basis for a number of reasons, not the least of which is the matter of deferment of medical school graduates for military service, presently limited to one year. There are other equally cogent reasons why such a plan would not be feasible, among others the time that would be added to that already required to prepare the young graduate for practice, already considered by many as over-long, and the effect such a course would have on men preparing for the practice of a specialty.

There remains then the alternative of reducing the number of available internships by curtailing the number of approved hospitals, by limiting the number of internships in each hospital, or by a combination of both these means. An arbitrary limitation in the number of approved hospitals could not be justified in principle or from the standpoint of the legality of such action. Certainly such an approach would in no way solve the problem of the individual hospitals that would be involved. In the past, the Council has attempted to effect a reduction in the number of internships through requesting hospitals to limit on a voluntary basis the number of internships offered. This proposal was not successful, principally, it is believed, because the plan was not well enough understood and because it came at a time when there was an increased demand for interns due to the induction into the military services of a large number of residents with a consequent shortage of house staff at this level. More recently the Advisory Committee on Internships recommended a provision that hospitals must maintain an intern occupancy rate of at least two-thirds of the requested number of interns in order to qualify for continued approval. This requirement placed the responsibility for determining the numbers of internship appointments on the individual hospitals and was, in effect, a self-regulatory mechanism. The "two-thirds rule," however, has not been activated.

There appears, then, to be no simple solution to this multifaceted problem. A continuing reevaluation of hospitals approved for intern education must be and is being made. Hospital staffs must critically evaluate their potential for training interns and seek other means for providing the services for which interns are ordinarily responsible, if through that self-appraisal it is evident that a sound educational program cannot be organized and carried out. Larger hospitals, particularly those with complete house staff structures from clerkships through residencies, should analyze realistically the duties and responsibilities of all members of the house staff and appoint interns only in such numbers as are justifiable from the standpoint of sound training and not convenience or service. Through the concerted efforts of all concerned with intern education, the accrediting agency, medical educators, hospital staffs and administrators, and others, a solution to the intern shortage can and must be found. It will require, however, a thorough understanding of the problems involved, a realistic and forceful approach, and the complete cooperation of the organizations, institutions, and individuals involved if the objective is to be reached.

PHYSICIANS FOR ARMED FORCES

Spokesmen for the Office of the Assistant Secretary of Defense for Health and Medical Affairs have provided THE JOURNAL with certain additional information regarding the editorial in the September 5 issue entitled "Armed Forces Faced with Surplus of Medical Officers." This information will be of interest to physicians liable for military service. The spokesmen reported that several actions have been taken to minimize the impact on the military services of the large number of volunteers referred to in the earlier editorial. The principal actions taken, which it is said will mitigate the problem, involve the interservice transfer of volunteer physicians from the Army to the Navy and the Air Force and the postponement of active duty orders for the present for the majority of the 466 reservists commissioned in the Army through the August Selective Service draft call.

Defense officials stated that as a result of these actions almost two-thirds of the 1,200 physicians referred to in the editorial will not enter on active duty in the Army, Navy, or Air Force during this fiscal year. They also emphasized that the armed forces will have on duty by June, 1954, an estimated 2,400 doctors less than they had the previous year. The Defense Department spokesmen concluded by stating that it appears at this time that it will not be necessary to have any further involuntary calls of physicians for at least 12 months.

This additional information is encouraging, and, if the proposed plans are carried to completion, they will do much to alleviate the uncertainty and doubt that has arisen over the actual need for physicians in the armed forces. It obviously will be necessary for such plans to be reviewed from time to time, for example, 12 to 15 months from now, when the need for physicians may become more acute, and reports to keep the medical profession informed will appear in THE JOURNAL as indicated. In the meantime, questions on medical military matters can be directed to the office of the Council on National Emergency Medical Service, American Medical Association.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

One of the most significant developments in the history of hospital-physician relationships was achieved at the recent annual session of the American Hospital Association in San Francisco. The House of Delegates of the AHA unanimously adopted the report of the Joint Committee on Hospital-Physician Relationships, which had already been unanimously approved by the House of Delegates of the American Medical Association last June.

This action was the culmination of many months of joint meetings by trustees of the AHA and the A.M.A. I personally took part in most of those sessions and know the careful thinking and the hard work that went into the drafting of the agreement. As Dr. Edwin L. Crosby, immediate past-president of the AHA, so ably stated: "This is a milestone in the development of better understanding between physicians and hospital administrators. It is an indication that every possible effort is being made by doctors and hospitals to provide the highest quality care to patients."

As far as I know, this was the first time that a joint committee of A.M.A. and AHA trustees had ever been formed to iron out the mutual problems of doctors and hospitals and to develop working procedures that would accrue entirely to the benefit of the patient. Here are the guiding principles that were embodied in the joint report:

"1. The general purpose of hospitals and physicians is to aid each other in the delivery of the best possible medical care to patients. To attain such a purpose requires full cooperation among medical staffs, governing boards and administrative heads of hospitals. One important method of attaining this objective is that duly designated representatives of the medical staff shall have free and direct access to the governing board with due consideration to the position of the administrator as chief executive officer of the hospital. The various methods by which the medical staff may have access to the hospital governing board follow.

"a. The executive committee of the medical staff and a committee of the governing board with the hospital administrator can serve as a joint committee.

"b. Representatives of the medical staff can serve as members of the medical staff committee of the governing board with the hospital administrator.

"c. Representatives elected by the medical staff can attend meetings of the hospital governing board.

"d. Members of the medical staff can be members of the hospital governing board.

"2. The professional evaluation of chiefs of service and members of the medical staff should be the responsibility of the medical profession. The method of selection of these individuals must be subject to local arrangements and local conditions. In any such arrangement, however, the principle of the freedom of the staff to make recommendations, subject to the approval of the hospital governing board, should be recognized.

"3. The medical profession and the hospitals recognize that certain special services, such as anesthesiology, pathology, radiology, and physical medicine, are integral parts of the practice of medicine and of the services necessary for hospital patients. Physicians in these fields should have the professional status of other members of the medical staff. Chiefs in these specialties must assume also the administrative responsibilities and relationships customarily associated with such positions.

"4 The right of an individual to develop the terms of his services on the basis of local conditions and needs is recognized, but such contractual arrangements should in all cases ensure (a) the policy of professional incentive for the physician, and (b) progressive development of the hospital departments involved, in order that increasingly improved services to patients may be rendered. Moreover, a physician shall not dispose of his professional attainments or services to any hospital, lay body, organization, group, or individual, by whatever name called, or however organized, under terms or conditions which permit exploitation of the patient, the hospital, or the physician.

"5. The chief of a hospital department may have access to financial information regarding his department.

"6. It is desirable that means should be provided at local, state and national levels for review of problems of individual hospital-physician relationship by organized medical and hospital groups."

The joint report consisted of 11 typewritten pages, from which the guiding principles enumerated above are excerpted. Although the statement was plainly worded and constructed so as to minimize the chance of misinterpretation, an erroneous story by the United Press did result and served to becloud an otherwise successful and enthusiastic meeting.

Nowhere in the entire report was there anything to advocate the lumping of all hospital expenses so patients would only have to pay one bill, as was incorrectly stated in the wire service story. This misleading news item set off a chain reaction that was heard across the country, but the UP failed to run a correction even when provided with a joint clarifying statement by Dr. Crosby and myself.

Edward J. McCormick, M.D., Toledo, Ohio.

ORGANIZATION SECTION

NEW A. M. A. TELEVISION FILMS

Four filmed television programs for presentation over local TV outlets will be ready for distribution by the American Medical Association on Oct. 1. The films will be made available to state and county medical societies without charge as an A. M. A. service. Designed to provide authentic medical information for the general public in an attractive package, the films are expertly produced and of exceptional quality. They offer local medical societies an excellent new public relations vehicle for use on television. TV rights on all four shows are the exclusive property of the American Medical Association. Any showing of the films on local stations must be under the auspices of the county or state medical society.

Two of the films, "Operation Herbert" and "A Citizen Participates," run 28 minutes, and a third, "Your Doctor," is a 15 minute film. The fourth program is a series of six five-minute films called "What to Do."

"Operation Herbert," starring stage, screen, and television actor Jackie Kelk, tells the story of a young biology instructor who undergoes an appendectomy. To prove a point with penny-pinching Aunt Agatha and to win the favor of his attractive nurse, Kelk uses homemade visual aids to show that medical care costs have not risen as high or as fast as the general cost of living.

"A Citizen Participates" is a documentary-type report on a small town that needs a physician. Citizen Bert Henderson, a local merchant, enlists the aid of a service club and initiates the campaign that makes his community attractive to a prospective doctor. Although this film is being distributed for nontheatrical showing by Young America Films, the A. M. A. has exclusive rights for TV showings.

"What to Do," a series of six five-minute features, answers some of the commonest home medical questions. Nancy Craig, ABC women's commentator, shows "what to do" in using a thermometer, applying artificial respiration, maintaining a medicine chest, and in emergency treatment of colds, abdominal pains, and headaches.

Fourth in the new A. M. A. TV film series is Louis de Rochemont's story of medical service in America, "Your Doctor." The 15 minute documentary spotlights medical student Edwin McGee and rural practitioner Dr. George Bond. The film is being released to television audiences for the first time.

In order to assure availability and avoid conflicting bookings, state and county medical societies are urged to arrange for the films well in advance of presentation. Prints may be secured from the A. M. A.'s TV Film Library, 535 North Dearborn Street, Chicago 10, Ill.

THE ST. LOUIS CLINICAL SESSION

Arrangements are being completed for the seventh annual Clinical Session of the American Medical Association Dec. 1-4 in St. Louis. This year's program has been designed to give the general practitioner an opportunity to see and hear the latest developments in medicine. Such topics as chest injuries, compression fractures of the vertebra, chronic pancreatitis, weed poisoning, and chronic arthritis—drugs and vaccine therapy, will be presented. Special features include fracture demonstrations; problems of delivery, with manikin demonstrations by leading obstetricians; traffic accidents, an exhibit symposium combining the experiences of physicians, the National Safety Council, and police departments; and diabetes, including exhibits and question-and-answer conferences in an adjoining room.

The Jefferson Hotel has been selected as the headquarters for House of Delegates sessions and reference committee meetings. All other features, the Scientific Exhibit, lectures, motion pictures, color television, and the Technical Exhibit, will be presented at the Kiel Auditorium. There will be more than 80 exhibits in the Scientific Exhibit. The Technical Exhibit will feature about 150 displays covering all types of office and medical practice needs. Plan now to attend this meeting.

NEW EXHIBITS ON ACCIDENTS AND IMMUNIZATION

Two new health education exhibits are now available from the A. M. A.'s Bureau of Exhibits. The first exhibit, "Home Accidents," shows pictorially the primary causes of accidents and their prevention in the various age groups, ranging from babies to teenagers and the aged. It points up the leading causes of death—burns, suffocation, falls, and poisons. Minimum space required for this exhibit is 10 by 6 feet. The other exhibit, on immunization, deals with several preventive agents used in fighting such diseases as smallpox, diphtheria, whooping cough, and tetanus. A question-and-answer box is included to take care of the most commonly asked questions. Primarily designed for small groups, this portable exhibit measures 44 inches by 4 feet. Both exhibits may be secured from the Bureau of Exhibits for showing at local meetings by state and county medical societies.

STATE MEDICAL JOURNAL CONFERENCE

The 1953 State Medical Journal Conference will be held Nov. 9 and 10 at American Medical Association headquarters. Sponsored by the Advisory Committee of the SJAB and approved by the Board of Trustees of the A. M. A., this meeting will be similar to the two day seminar held in 1951. Dr. L. Fernald Foster of Bay City, Mich., a member of the advisory committee, as chairman of the conference has arranged a program that will be of interest to both editors and business managers of the state medical publications, for whose benefit the conference has been scheduled. Topics to be presented include "The History of Pharmaceutical Advertising," "Printing Costs," "State Medical Journal Formats," and "Responsibilities of an Editor."

NEW PUBLIC RELATIONS MANUAL

A new American Medical Association publication, entitled "℞ PR," will be mailed to all Association members after Sept. 28. This prescription for medical public relations is in the form of a manual for physicians. The first half of the booklet is devoted to discussions of doctor-patient relationships; the second section takes up the business aspects of medical practice. The public relations ideas, suggestions and techniques contained in the manual constitute the combined thinking of 50 PR-minded practicing physicians from all parts of the United States. In the introduction it is stated that "every complaint of the public is a danger signal—a symptom of the public ill will, justified or unjustified, harbored against some physicians and some aspects of medical care." The booklet points out that "public relations is every physician's responsibility." The manual also will be made available to medical students, interns, and residents.

NEW SERIES OF RADIO TRANSCRIPTIONS

What medicine is doing to overcome the principal causes of death in the world today is the theme of a new series of radio transcriptions released by the American Medical Association Sept. 15. The 13-program series—"Medicine Fights the Killers"—covers the following subjects: coronary thrombosis, rheumatic heart disease, lung cancer, leukemia, hypertension, accidents, nephritis, premature births, tuberculosis, pneumonia, diabetes, suicide, and poliomyelitis. Prepared by the Bureau of Health Education, these transcriptions may be used by local radio stations under the auspices of state and county medical societies.

MEDICAL NEWS

CALIFORNIA

Plague Infection.—According to the U. S. Department of Health, Education, and Welfare a specimen obtained Aug. 13 in San Mateo County was found to be positive for plague. The specimen consisted of 25 fleas (Hystrichopsylla dippiei, Malaraeus telchinum, and Atyphloceras multidentatus) collected from the nest of a field mouse (Microtus californicus) about 2 miles south of the San Francisco city limits.

CONNECTICUT

Hospital News.—The Hartford Hospital's first guest speaker on its Saturday morning 11 o'clock series will be Dr. Sidney Farber, pathologist, Children's Medical Center, Boston, and director of research, Children's Cancer Research Foundation, who will discuss "Progress in Research in Lipid Metabolic and Related Disorders," Sept. 26.

GEORGIA

Eye Bank Donations.—The Ponce de Leon Eye, Ear, Nose and Throat Infirmary, Atlanta, which is affiliated with the national Eye Bank for Sight Restoration, is offering its services for those who wish to donate their eyes to the eye bank at time of death. Physicians may secure forms necessary for this service. All arrangements will be made by the infirmary after notification by the physician.

Personal.—Dr. Edward J. Smith, Hahira, was recently honored at a dinner given by the community in recognition of his 52 years of service.——Dr. William H. Tanner, Newnan, was recently the guest of honor at a community-wide surprise party given by the Rico Civic Club in honor of his 50 years of medical practice. A gold pen and pencil set was presented to Dr. Tanner.

ILLINOIS

Narcotic Violation.—Dr. Henry W. Bond, Galesburg, who pleaded not guilty in the U. S. District Court at Peoria to violation of USC Title 26, Section 2554, on July 29, was found guilty by Judge Leroy Adair, who suspended sentence and placed him on probation for five years.

Psychiatry Lectures in Winnetka.—The North Shore Health Resort, 225 Sheridan Road, Winnetka, invites all physicians to attend its fourth annual lecture series, which will have as its theme "Treatment in Psychiatry." The lectures will be given the first Wednesday of each month (second Wednesday in May) from October, 1953, to June, 1954. Opening the series Oct. 7 will be "The Problem of Psychiatric Referral" by Dr. Harold G. Wolff, professor of medicine, Cornell University Medical College, New York.

Chicago

Meeting of Chest Physicians.—A joint meeting of the Illinois Chapter of the American College of Chest Physicians and the eighth annual postgraduate course on diseases of the chest will be held at the Knickerbocker Hotel, Chicago, Oct. 1, at 6 p. m. The guest speaker will be Dr. Alvis E. Greer, Houston, Texas, president, American College of Chest Physicians. At 8:30 p. m. Dr. Albert H. Holland, medical director, Armour Laboratories, Chicago, will discuss "Techniques of Aerosolization." At 9 p. m. Dr. Coleman B. Rabin, New York, will serve as moderator for an x-ray symposium in which the collaborators will be Drs. Alvan L. Barach, New York, Benjamin M. Gasul and Jerome R. Head, Chicago, and Harold G. Trimble, Oakland, Calif. Physicians are cordially invited to attend.

IOWA

Dr. Hennessy Honored.—About 1,000 persons from Calmar and the surrounding area honored Dr. Felix A. Hennessy at a surprise reception at the St. Aloysius church auditorium in recognition of his 45 years of service. Dr. Hennessy, a past president of the Iowa State Medical Association, is on the staff of the Decorah Hospital and of St. Joseph's Hospital in New Hampton. He is a past president of the Iowa Tuberculosis and Health Association and presently is president of the Winneshiek County chapter. For many years he served as president of the Calmar school board.

KENTUCKY

Gifts to Rural Scholarship Fund.—The Louisville Courier-Journal and Louisville Times Foundation has contributed $800 to the Kentucky Rural Medical Scholarship Fund and has indicated that similar contributions will be forthcoming on an annual basis for three additional years. This revolving fund was established in 1946 by the Kentucky State Medical Association in cooperation with the University of Louisville School of Medicine.

Preventive Medicine Program.—The University of Louisville School of Medicine recently received from the W. K. Kellogg Foundation of Battle Creek, Mich., a grant of $141,000, to be used for a five year plan in the field of preventive medicine. Under the new teaching program, which will be initiated this fall, a group of students will be assigned to persons or families needing medical care and will follow the patients' progress. The program will be used in the departments of medicine, surgery, pediatrics, obstetrics and gynecology, psychiatry, and community health.

MASSACHUSETTS

France Honors Dr. Churchill.—By decree of the president of the French Republic, Dr. Edward D. Churchill, Boston, was granted the Cross of Knight of the Legion of Honor "as a token of appreciation for his remarkable achievements in the field of surgery and of gratitude for his outstanding contribution in fostering closer cooperation between the scientists of the two countries." The decoration was bestowed, July 14, by M. François Charles-Roux, consul general of France in Boston.

Dr. Feldberg to Give Dunham Lectures.—The faculty of Harvard Medical School, Boston, announces that the Edward K. Dunham lectures will be presented by Dr. Wilhelm Siegmund Feldberg, head of the physiology and pharmacology laboratory, National Institute for Medical Research, London. He will make the following presentations: Oct. 5, Physiology of the Autonomic Nervous System; Oct. 7, Chemical Transmission of Nerve Effects; and Oct. 9, Special Problems of Chemical Transmission of Nerve Effects. The lectures will be given at 5 p. m. in the Harvard Medical School, Amphitheatre, Building D. These annual lectures, which were established to "bind closer the bonds of fellowship and understanding between students and investigators in this and foreign countries," are "free and open to the faculty and students of the Harvard Medical School and College, and all other interested professional persons who may profit by them."

MICHIGAN

Hospital News.—Dr. Harold A. Ott has resigned as medical director of Florence Crittenton Hospital, Detroit, a position which he filled on a part-time basis, and will devote his entire time to private practice. On Oct. 1, Dr. Edward S. Zawadzki will assume the directorial position, in addition to his duties as pathologist and director of clinical laboratories.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Dr. Rector Retires from Cancer Control Program.—Dr. Frank L. Rector, Ann Arbor, has retired from active participation in the cancer control program after 23 years of service. He served as midwestern field representative of the American Cancer Society for 11 years, cancer consultant for the Michigan Department of Health for 5 years, and secretary of the Cancer Control Committee, Michigan State Medical Society for the past 7 years. Dr. Rector prepared the text of "The Story of Cancer for High Schools," recently published by the committee. He has spoken to more than 925 high school audiences and to an equal number of adult lay groups. In 1952 he received the first award of the Public Health Cancer Association of America for his contribution to cancer education and control, and in March, 1953, the Michigan State Medical Society presented him with a scroll of appreciation for his efforts in lay cancer education.

MINNESOTA

Dr. Laird Honored.—Dr. Arthur T. Laird, who retired from the Moose Lake State Hospital staff July 15, was honored by the hospital employees and their families at a picnic held July 7. Dr. Laird, who was formerly a member of the medical staff at Trudeau Sanatorium, Saranac Lake, N. Y., came to Nopeming Sanatorium as superintendent in 1911 and served in this capacity for 30 years. During World War I, he was chosen by the Rockefeller Foundation to work with the French government in demonstrating the most recent advances in the care of tuberculosis patients.

MISSISSIPPI

Fifty Year Club.—The following physicians recently became members of the 50 year club of the Mississippi State Medical Association: George M. Barnes, Belzoni; William W. McBryde, Ethel; George W. F. Rembert and John S. McIntosh, Jackson; John M. Wright, Hernando; James R. Hill, Corinth; and B. Lampton Crawford, Tylertown.

NEW JERSEY

Award for Residents and Interns.—The New Jersey Chapter of the American College of Surgeons announces that (1) a yearly prize of $100 will be given to the surgical resident in a New Jersey hospital who presents the best published paper on a surgical subject and (2) a yearly prize of $100 will be given to the intern in a New Jersey hospital who presents the best unpublished paper on a surgical subject. For information, contact Dr. Benjamin Daversa, 209 Passaic Ave., Spring Lake.

Workshop at Kessler Institute.—The Advisory Committee on Rehabilitation of the Medical Society of New Jersey will sponsor a workshop on employment of the physically handicapped at the Kessler Institute for Rehabilitation, West Orange, Oct. 2, to which physicians, nurses, therapists, social workers, and other rehabilitation personnel are invited. Dr. Henry H. Kessler, medical director of the institute, will make the presentation for medicine. Three panels representing special disability groups have been scheduled for the afternoon program.

Personal.—Dr. Clement M. Jones, Bayonne, was recently awarded the honorary degree of doctor of science by Lincoln University, Oxford, Pa.——Dr. Marcus W. Newcomb, Browns Mills, was guest of honor at a testimonial dinner in recognition of his 50 years as a practicing physician and 34 years as director of the Marcus W. Newcomb Hospital for Chest Diseases, New Lisbon.——Dr. John R. Pavia, East Orange, has been appointed medical director of Public Service Electric and Gas Company and Public Service Coordinated Transport. Dr. Pavia has been affiliated with these organizations in medical work since 1937.

NEW YORK

Cardiac Rehabilitation Program at West Point.—The Orange County Heart Association will present a program dealing with rehabilitation and employment problems at its annual meeting and dinner, Sept. 29, at the Hotel Thayer, West Point. Dr. Leonard J. Goldwater, professor of industrial hygiene, Columbia University College of Physicians and Surgeons, and founder of the Cardiac Work Classification Clinic, Bellevue Hospital, New York City, will be guest speaker. Physicians are invited.

New York City

Radiology Services Consolidated.—Dr. Marcus D. Kogel, city commissioner of hospitals, and Dr. Currier McEwen, dean of the New York University College of Medicine, announce the consolidation of the departments of diagnostic radiology and radiation therapy into a unified department of radiology at Bellevue Hospital Center. Dr. Maxwell H. Poppel, chairman, department of radiology, New York University College of Medicine, has been appointed director of this new service, and Dr. Sidney Rubenfeld, clinical professor of radiology at the college, has been named director of the new division of radiation therapy. Dr. Poppel, who will direct all radiological activities at Bellevue, University, and Gouverneur hospitals, all of which are affiliated with the New York University-Bellevue Medical Center, is also consulting radiologist to the U. S. Naval Hospital at St. Albans, Veterans Administration Hospital, New York, and St. Francis Hospital, Poughkeepsie. During his service as commander in the Naval Reserve during World War II, he was director of radiology, U. S. Naval Hospital, Chelsea, Mass. Dr. Rubenfeld, who served five years in World War II, is attending consultant in radiology at Veterans Administration Hospital, New York, director of the isotope service at Bellevue Hospital Center, and a member of the Oak Ridge board for study of heavy isotope sources.

Symposium on Diabetes.—The New York Diabetes Association will hold a symposium day on diabetes, Oct. 8, at the Memorial Center for Cancer and Allied Diseases, 410 E. 68th St. Presentations by physicians include:

Cyril N. H. Long, New Haven, Conn., Hormonal Control of Carbohydrate Metabolism.
William C. Stadie, Philadelphia, Action of Insulin.
Herman O. Mosenthal, New York, Insulin and Complications of Diabetes—Endogenous and Exogenous Insulin.
Franklin B. Peck, Indianapolis, Indications for the Use of Various Insulins.
David Hurwitz, Boston, Management of Diabetes During Pregnancy.
Lawrence E. Hinkle Jr., New York, Effects of Life Situations and Emotions on Management of Diabetes.
W. Ross McCarty, New York, Management of Surgical Infections in Diabetes with Special Reference to Streptokinase-Streptodornase.
Herbert Pollack, New York, Nutritional Management of Diabetes.

Discussants include Drs. John S. L. Browne, Montreal, Canada, Martin G. Goldner, Brooklyn, and Benjamin I. Ashe, William P. Given, and Elaine P. Ralli, New York. Physicians, medical students, and other professional personnel are invited. Advance registration is necessary.

OHIO

Hospital at Cambridge Closes.—Dr. George F. Swan, chief of staff, announces that, because of his recent illness, the Swan Hospital, Cambridge, has discontinued operation after 23 years of service. He and his brother, Dr. Reo M. Swan, who has been associated in the operation of the hospital, will continue in practice. Dr. George Swan is a former member of the council of the Ohio State Medical Association.

Plaque Dedicated to Physicians in Indian Wars.—As part of the Ohio sesquicentennial celebration, the Ohio State Medical Association and the Ohio Archaeological and Historical Society have erected a marker on the site of Fort St. Clair in honor of physicians who took part in the Indian wars. The marker lists the physicians' names and shows on a sketch the major events in the campaigns. Participating in the dedication ceremonies were Drs. Augustus L. Ross Jr., West Alexandria, president of the Preble County Medical Society; Merrill D. Prugh, Dayton, president-elect of the Ohio State Medical Association; Paul A. Davis, Akron, president of the Ohio State Medical Association; and Jonathan Forman, editor of the *Ohio State Medical Journal*.

OREGON

Society News.—At its annual meeting at Oregon Caves, the Southern Oregon Medical Society elected Drs. Robert W. Sleeter, Medford, president; John W. Bradshaw, Ashland, vice-president; and Earl L. Lawson, Medford, secretary-treasurer.

University News.—The University of Oregon Medical School, Portland, recently announced the following appointments: Drs. Harold Tivey, assistant professor of medicine; William W. Krippaehne, instructor in surgery; Sarah E. Stewart, instructor in pediatrics; Tyra T. Hutchens and James H. Lium, assistant professors of clinical pathology; Robert D. Koler, clinical associate in medicine; Ruth I. Kukko, instructor in medicine; and Jesse L. Ray, clinical instructor in obstetrics and gynecology. ——The University of Oregon, Portland, recently received grants, totaling $39,880, from the Atomic Energy Commission. Of this sum, $25,000 will be used for the continuation of a hematology research project under the direction of Drs. Edwin E. Osgood and Arthur J. Seaman, division of experimental medicine, and $4,100 for a radium research project being carried on by Dr. Frank B. Queen, department of pathology.

Personal.—Dr. Harold A. Press, Portland, formerly director of the medical program analysis branch of the Veterans Administration, has been appointed regional medical consultant of the National Foundation for Infantile Paralysis for 10 Pacific and western states. His office will be in San Francisco. ——At the annual meeting of the Mental Health Association of Oregon, honorary life membership was voted for Dr. Ferdinand H. Dammasch, Portland, sponsor of recent legislation to build a hospital for aged, mentally ill persons.——Dr. Marlowe H. Schaffner, Cottage Grove, has been appointed medical director of the Songa Mission Hospital located in the Belgian Congo, Africa, where he will supervise a 350 patient leper colony. Dr. Schaffner and his family will spend several months in Europe before going to the new post.——Dr. Rudolph E. Kleinsorge, Silverton, has been made president of the state board of higher education, of which he has been a member since 1941. Dr. Kleinsorge, a past president of the Marion County Medical Society, served on the Silverton school board for nine years.——Dr. William Horsfall, Coos Bay, was honored at the annual convention of the Oregon State Aerie of Eagles at Coos Bay. The entire convention was dedicated to him by the Coos Bay Aerie and a 50 year jewel was presented to him. Dr. Horsfall, the oldest member of the aerie, has been its physician since 1904.

UTAH

Symposium on Atomic Energy.—The University of Utah College of Medicine, Salt Lake City, will present a symposium on medical aspects of atomic energy, Oct. 7-9. The program includes discussion of medical effects of atomic weapons, civil defense considerations, and the clinical and research applications of radioactive elements. Speakers will be scientists from the atomic energy project and principal university research laboratories. For information regarding registration, contact the Office of the Division of Graduate and Postgraduate Medical Education, 175 E. 21st South, Salt Lake City.

VIRGINIA

Meeting on Crippled Children.—The annual Conference on Crippled Children will be held at the Medical College of Virginia, Richmond, Oct. 5-6, under the sponsorship of the Virginia Council on Health and Medical Care, at the request of the Nemours Foundation of Wilmington, Del. The theme of the conference is "Growth and Development of the Crippled Child." Dr. Samuel M. Wishik, professor of maternal and child health, University of Pittsburgh, will present medicine's responsibility, and Bess Goodykoontz, director of comparative education, Division of International Education, Department of Health, Education, and Welfare, Washington, D. C., will present education's responsibility. Physicians are invited. Information may be obtained from Edgar J. Fisher Jr., director, Virginia Council on Health and Medical Care, 102 E. Franklin St., Richmond 19.

Personal.—William T. Sanger, Ph.D., president of the Medical College of Virginia, Richmond, was recently elected president of the National Society for Crippled Children and Adults, Inc.——Dr. Frederick L. McDaniel, Richmond, for four years assistant to the commissioner of the state department of mental health and hospitals, has resigned to accept a position with the Central Inspection Board of the American Psychiatric Association. ——A portrait of Dr. William Tate Graham was presented to the Crippled Children's Hospital of Richmond by the staff of the hospital, which he has served as surgeon-in-chief since its founding.——The Medical College of Virginia, Richmond, at its 116th commencement bestowed honorary degrees on Dr. Jack Walter Witten, North Tazewell (Master of Humane Letters), Dr. Richard Henry Eanes, Washington, D. C. (Doctor of Laws), and Dr. Richard Hugh Wood, Atlanta (Doctor of Science).

WISCONSIN

State Medical Meeting in Milwaukee.—The annual meeting of the State Medical Society of Wisconsin will be held in the Milwaukee Auditorium Oct. 6-8 under the presidency of Dr. Joseph C. Griffith, Milwaukee. On Oct. 5 there will be a special luncheon for all delegates, councilors, officers, and invited guests, with Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, as the principal speaker. Each morning, 9-10, teaching demonstrations will be presented in anatomy, obstetrics and gynecology, fractures, cerebral palsy, and gross pathology. Twenty out-of-state speakers will participate in the scientific sessions. On Tuesday, special emphasis programs will be given in the following subjects: Dr. John W. Pender, Rochester, Minn., will discuss "General Anesthesia for the Patient with Cardiac Disease," and Dr. William O. McQuiston, Chicago, "Anesthesia for Cardiac Surgery." Dr. David A. Boyd Jr., Rochester, Minn., will deliver the Rogers Memorial lecture on "Psychological Needs of the Medically and Surgically Ill Patient." Dr. Joseph C. Aub, Boston, will lecture on "The Relation of Hormones to Carcinoma," under the sponsorship of the Wisconsin division of the American Cancer Society. Dr. G. Edmund Haggart, Boston, will present "Management of Low Back and Sciatic Back Pain." Dr. William T. Green, Boston, will lecture on "Reconstructive Surgery in Poliomyelitis" unde [illegible] the National Foundation for Infantile [illegible] will also present "Early Treatment of Poliomyelitis" during the Tuesday afternoon scientific assembly, when Dr. Paul L. Shallenberger, Sayre, Pa., will discuss "Lesions of the Lower Colon," and Dr. Pender "Complications in Anesthesia Related to Cortisone Therapy." The Milwaukee Art Institute, which is presenting an art exhibit entitled "The Story of Medicine in Art," will hold a special reception for physicians and their wives at 5:30 p. m. at the Hotel Pfister, preceding the buffet dinner and special program at which Lejaren à Hiller, New York, photographer and illustrator, will be the featured speaker.

The Wednesday afternoon scientific assembly will consist of the following presentations:

Arterial Hypertension as Determined by the Success of Certain Medical or Surgical Procedures, Joseph H. Hafkenschiel Jr., Philadelphia.
Nonoperative Treatment of Stress Incontinence in Women, Lawrence R. Wharton, Baltimore.
Thoracic Trauma, William M. Tuttle, Detroit.
Newer Methods of Diagnosis and Therapy in Office Gynecology, Conrad G. Collins, New Orleans.

Other out-of-state speakers on the Wednesday program are Dr. Charles K. Friedberg, New York, who will lecture on "Electrolyte Disturbances of Heart Disease" and Brig. Gen. Elbert DeCoursey, director, Armed Forces Institute of Pathology, Washington, D. C., who will speak on "The Pathology of Hemorrhagic Fever." A program on obstetrics and gynecology will also be presented Wednesday morning. The annual dinner, dance, and floor show are scheduled for Wednesday evening.

On Thursday Dr. J. Barrett Brown, St. Louis, will conduct a round-table discussion on "Surgical Repair of Radiation Lesions, Including Those of Atomic Origin" and Dr. Oliver P. Kimball, Cleveland, will conduct one on "Epilepsy in Relation to Inheritance." Thursday's special interest programs include pediatrics, radiology, and surgery. The section on ophthalmology and otolaryngology will hold a luncheon meeting at the Hotel Shroeder. At 1:30 p. m. Dr. Hermann M. Burian, Iowa City, will present "Evaluation of Diagnostic Methods in the Examination of Neuromuscular Anomalies of the Eye." At 2:40 p. m. Dr. Oscar J. Becker, Chicago, will consider "The Septum in Relation to Rhinoplastic Surgery." The closing scientific assembly at the Hotel Shroeder, will consist of the following presentations:

Robert M. Janes, Toronto, Canada, Rounded Shadows in the Chest.
Traian Leucutia, Detroit, Newer Developments in Radiation and Chemotherapy for the Treatment of Cancer.
Milton J. E. Senn, New Haven, Conn., What the Family Physician Should Know About Emotional Problems of Children.

Dr. Janes will also give a lecture on "Breast Carcinoma."

Fire Hazards in Hospitals.—A lecture and demonstration on "Fire and Explosion Hazards in Hospitals and Their Control" will be conducted by Dr. George J. Thomas, professor of anesthesiology, University of Pittsburgh School of Medicine, at 3 p. m., Oct. 2, at Marquette University School of Medicine, 561 N. 15th St., Milwaukee. The program, which is open to all those interested, is sponsored by the Wisconsin Society of Anesthesiologists with the cooperation of Marquette University School of Medicine. Dr. Thomas has worked in close cooperation with the explosives division of the U. S. Bureau of Mines in Pittsburgh since 1938 in research on the prevention of fires and explosions with flammable anesthetic agents. For information, contact Dr. Richard Foregger, BLuemound 8-5848, Milwaukee.

GENERAL

Mine Workers to Build 10 Hospitals.—The United Mine Workers Welfare and Retirement Fund has announced plans to build 10 hospitals in Virginia, West Virginia, and Kentucky, with a total of about 1,000 beds. Construction has been started on the 200 bed unit in Beckley, W. Va., which will maintain a school of practical nursing.

Fulbright Awards Offered.—Twenty U. S. government awards (1954-1955) for university lecturing and 10 awards for advanced research under the Fulbright Act have been announced for Japan. Application forms may be obtained from the Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Ave., N.W., Washington 25, D. C. Applications must be submitted before Oct. 15.

Meeting of Clinical Society.—The annual meeting of the Gulf Coast Clinical Society will be held in Mobile, Ala., Oct. 15-16. Guest speakers include:

Carl A. L. Binger, New York, Psychotherapy of Everyday Practice.
Edgar A. Hines Jr., Rochester, Minn., Medical Aspects of Peripheral Vascular Diseases.
Robert Lich Jr., Louisville, Chronic Pyelonephritis.
Joseph H. Farrow, New York, Differential Diagnosis of Lumps in the Breast.
Henry T. Bahnson, Baltimore, Aortic Surgery.
Armand J. Quick, Milwaukee, The Hemorrhagic Diseases.

Drs. Tinsley R. Harrison and Champ Lyons, Birmingham, Ala., will participate in a clinical pathological conference.

National Foundation Fellowships.—The National Foundation for Infantile Paralysis announces a limited number of additional postdoctoral fellowships to candidates whose interests are research and teaching in medicine and the related sciences. The purpose is to increase the number of professional workers qualified to give leadership in the solution of basic and clinical research problems including those of poliomyelitis and other crippling diseases. The fellowships cover a period of from one to five years. Stipends range from $3,600 to $7,000 a year, with marital and dependency status considered in determining awards. Eligibility requirements include United States citizenship, sound health, and an M.D., Ph.D., or equivalent degree. Information may be obtained from: Division of Professional Education, National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

Insurance Medical Directors Meet in New York.—The Association of Life Insurance Medical Directors will hold its annual meeting at the Hotel Statler, New York, Oct. 14-16 under the presidency of Dr. Earl C. Bonnett, New York, medical director of the Metropolitan Life Insurance Company. Wednesday morning there will be a panel discussion on "Systolic Heart Murmurs" by Drs. Henry B. Kirkland, Edson E. Getman, K. Jefferson Thomson, and Harry E. Ungerleider, New York. Friday morning a panel on "Accident and Health-Hospitalization Insurance—A Problem for Mutual Understanding" will be presented by Dr. Ralph M. Filson, Hartford, Conn., Mr. Ralph T. Heller, and Mr. Wendell A. Milliman. The association luncheon will be held Wednesday, and the annual reception and informal dinner are scheduled for Thursday evening.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

	Sept. 12, 1953		
Area	Paralytic Type	Total Cases Reported	Sept. 13, 1952 Total

Industrial Health Conference.—The Upper Midwest Industrial Health Conference will be held at the Hotel Nicollet, Minneapolis, Oct. 2, under the sponsorship of the Minnesota State Medical Association, Minneapolis Chamber of Commerce, and Central States Society of Industrial Medicine and Surgery in cooperation with the Hennepin County Medical Society, Minnesota Academy of Occupational Medicine, and Minnesota Industrial Nurses Association. In the morning Dr. Orwood J. Campbell, Minneapolis, will serve as moderator for a panel discussion entitled "Health Service in Industry," and Dr. James R. Fox, Minneapolis, will moderate a panel discussion entitled "The Role of Psychology in Industry." The following presentations will be made during the afternoon session:

Injuries of the Hand, Albert T. Hays, Minneapolis.
Dermatology in Industry, Mr. Robert W. Plunkett.
Eye Injuries, Malcom A. McCannel, Minneapolis.

Dr. Leonard A. Scheele, Washington, D. C., Surgeon General, U. S. Public Health Service, will be the guest speaker at the dinner and evening session, 6:30-9 p. m.

Otolaryngologist Wanted in India.—The Vellore Christian Medical College in southern India, an international enterprise of the mission boards of Protestant church denominations in Canada, Britain, Australia, and the United States, is seeking a department head for its ENT staff. The college hospital has 550 beds, a dozen of which are allotted to the department of otolaryngology. The ENT outpatient department has a daily attendance of 50 to 60 patients. There are 175 students enrolled in the five medical classes. The program of teaching comprises 12 lectures to the fifth year students, sections for clinical work, rounds, and clinicopathological conferences. There is a large volume of clinical and operative work. The applicant should be a member of a Protestant church and a diplomate of the American Board of Otolaryngology, have three years of teaching experience, and be willing to serve for at least three years on a very modest salary. Details may be obtained from Miss Sarah Scudder Lyon, secretary, Vellore Christian Medical College Board, 156 Fifth Ave., New York 10.

Meeting on Surgery of Trauma.—The American Association for the Surgery of Trauma will hold its annual session at the Drake Hotel, Chicago, Oct. 1-3. Dr. Martin C. Lindem, Salt Lake City, will deliver the presidential address Friday morning. Dr. Paul R. Hawley, Chicago, will be toastmaster at the banquet, 8 p. m., where Frank G. Dickinson, Ph.D., director, A. M. A. Bureau of Medical Economic Research, will speak on "Pension Plans for Physicians." Ladies and other guests are invited. A film on "Transportation of the Injured Within the Hospital" will be presented by invitation by Dr. David R. Limbach, Flint, Mich., Friday, 8:30 a. m. Films on "The Principles of the Reduction of Fractures" and "Fractures of the Humerus," shown Saturday, 8:15 a. m., through the courtesy of the chief medical director, Veterans Administration, will be discussed by Dr. William A. Larmon, Chicago. The Edward D. Churchill lecture will be delivered Friday afternoon under the sponsorship of the Excelsior Club by Dr. Carl A. Moyer, St. Louis. The sessions will end Saturday morning with "Narrative Reports on the Management of Mass Civilian Casualties (The Story of Three Hurricanes)" by Drs. George J. Curry, Flint, Mich., George R. Dunlop, Worcester, Mass., and Hannibal L. Jaworski, Waco, Texas.

Medical Research Fellowships.—The National Research Council is accepting applications for postdoctoral research fellowships for 1954-1955. These awards, designed to offer research experience for promising individuals who look forward to investigative careers, do not provide practical experience in the clinical field. Ordinarily fellowships are not granted to persons over age 35. The following programs are announced:

1. Fellowships in cancer research, awarded by the American Cancer Society on recommendation of the committee on growth of the division of medical sciences, are available for study in all branches of the biological, chemical, and physical sciences and of clinical investigation applicable to the study of growth, typical or malignant. Citizens of the United States are eligible.

2. British-American exchange fellowships in cancer research, awarded by the American Cancer Society on recommendation by the committee on growth, are offered to citizens of the United States for advanced study in Great Britain in specialized fields pertaining to the problem of cancer. Similar fellowships are awarded by the British Empire Cancer campaign to British scientists for research in the United States.

3. Fellowships in the medical sciences, supported by the Rockefeller Foundation and the Lilly Research Laboratories, are administered by the medical fellowship board of the division. Fellows are expected to devote themselves to research in the basic medical sciences. The Rockefeller fellowships are open to citizens of the United States and Canada; the Lilly fellowships only to citizens of the United States.

4. Fellowships in tuberculosis, administered by the medical fellowship board under a grant from the National Tuberculosis Association and designed to promote the development of investigators in fields related to tuberculosis, are open to citizens of the United States, graduates of American schools.

5. Fellowships in radiological research are administered by the division's committee on radiology for the James Picker Foundation. Appointments are not limited to citizens of the United States.

Applications for 1954-1955 under any of these programs must be postmarked on or before Dec. 10. Fellowships are awarded in the late winter or early spring. Details may be obtained from the Fellowship Office, National Research Council, 2101 Constitution Ave., N.W., Washington 25, D. C.

Meeting of Vermont and New Hampshire Societies.—The fourth annual combined meeting of the Vermont State Medical Society, New Hampshire Medical Society, and the woman's auxiliaries will convene at Equinox House, Manchester, Vt., Oct. 4-6. Dr. Paul K. French, Burlington, Vt., is president of the Vermont society, and Dr. Joseph N. Friborg, Manchester, N. H., of the New Hampshire society. Preceding the official sessions, the golf tournament will be held at Equinox Links on Saturday, and the sports dinner on Sunday. All physicians are invited to attend the scientific session of the New Hampshire Heart Association in the Garden House at 3 p. m. Sunday. Out-of-state speakers will present the following papers on Monday:

Henry L. Bockus, Philadelphia, Post Cholecystectomy Syndrome. Diseases of the Gastrointestinal System.
Edward A. Edwards, Boston, Varieties of Digital Ischemia and Their Management.
Charles P. Emerson Jr., Boston, Recent Advances in Transfusion Therapy.

A Dutch treat cocktail party will be held in the Garden House at 6:30 p. m., preceding the banquet for which Dr. Howard J. Farmer, St. Johnsbury, Vt., will act as toastmaster. Major General Ernest N. Harmon, USA, Ret., Northfield, Vt., will speak on "Our Position of World Leadership." Sectional meetings will be held on Tuesday. Dr. Ruth Fox, New York, will participate in a panel discussion which will follow her presentation on "Basic Concepts in the Interpretation of Alcoholism as a Medical Condition." The section on anesthesiology will have a panel discussion on "Oxygen Want"; the section on ear, eye, nose and throat, a round-table conference on "Treatment of Complications of Ocular Surgery"; and the section on public health, a round-table discussion on "Present Day Problems in Public Health." Dr. Frederick W. Goodrich Jr., New London, Conn., will discuss "Experiences with 'Natural Childbirth'" before the section on obstetrics and gynecology. The section on internal medicine will have as guest speaker Dr. Joseph F. Ross, Boston, who will present "Immunohematologic Diseases."

CORRECTION

Blood Alcohol Concentration.—In a medicolegal abstract in The Journal, Aug. 1, 1953, page 1368, a technologist was quoted as testifying that a blood alcohol concentration of 0.28% means 2,800 mg. of alcohol per 100 cc. of blood. The statement quoted in the abstract appeared in the reported opinion of the Supreme Court of Colorado. Obviously what the technologist should have said is that 0.28% is equivalent to 280 mg. per 100 cc., or 2,800 mg. per 1,000 cc.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.
1954 Annual Meeting, San Francisco, June 21-25.
1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Meeting, Atlantic City, N. J., June 6-10.
1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct. 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5.9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9. Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Dental Association, Cleveland, Sept. 28-Oct. 1. Dr. Harold Hillenbrand, 222 E. Superior St., Chicago 11, General Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15. Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association of State and Territorial Health Offcers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* All centers where there are five or more candidates. Sept. 8-10 (Part I only). Candidates may file applications at any time, but the National Board must receive them at least six weeks before the date of the examination they wish to take. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16, 1954. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: All candidates must now pass a written examination. *Oral.* Philadelphia, Oct. 16-18. To be eligible, candidate must complete 36 months of training before Oct. 1. Final date for filing applications was May 1. Exec. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Sept. 30-Oct. 2, Chicago, Nov. 30-Dec. 2. The closing date for acceptance of applications for the San Francisco and Chicago oral examination was April 1. *Written.* October 19. The closing date for acceptance of applications was May 1. Exec. Sec.-Treas., Dr. William A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* New Haven, October. Final date for filing application was July 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, Kingshighway and Euclid Ave., St. Louis.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: *Written.* Various cities of the United States and Canada, Feb. 5. Application for examination or re-examination, as well as requests for resubmission of case reports, must be made prior to October 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: Chicago, Oct. 5-9. *Written.* Various Centers, January 1954. Final date for filing applications was July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written. Pathologic Anatomy and Clinical Pathology.* Chicago, Oct. 8-10. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Miami, Oct. 9-11; Indianapolis, Dec. 4-6. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Entire Examination.* San Diego, Oct. 29-31. Final date for receipt of case reports was June 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Proctology: *Part II. Oral and Written. Anorectal Surgery and Proctology.* Philadelphia, Sept. 19. Sec., Dr. Louis A. Buie, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Surgery: *Part I.* Oct. 28, 1953. March 31, 1954 and Oct. 27, 1954. *Part II.* New York City, Oct. 12-13; Chicago, Nov. 9-10; St. Louis, Dec. 14-15; Los Angeles, Jan. 11-12, 1954; Galveston, Jan. 15-16; Washington, Feb. 8-9; Cincinnati, March 8-9; New Orleans, April 12-13; Philadelphia, May 10-11; Boston, June 14-15. Sec., Dr. John B. Flick, 225 S. 15th St., Philadelphia 2.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 11. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Harvey, Samuel Clark ⊕ New Haven, Conn.; born in Washington, Conn., Feb. 12, 1886; Yale University School of Medicine, New Haven, 1911; became an Alonzo Clark fellow in pathology and instructor in pathology at Columbia University in New York; also served for one year as assistant resident physician in the Loomis Sanatorium in New York; from 1914 to 1917 was house officer in surgery and assistant resident in surgery at the Peter Bent Brigham Hospital in Boston and Arthur Tracy Cabot fellow in surgery at Harvard University in Boston; during World War I joined the medical corps of the U. S. Army and served in France as a major; on release from the armed forces in 1919, was made resident surgeon in the New Haven Hospital and instructor in surgery at his alma mater; the following year was promoted to assistant professor of surgery and in 1921 was named an associate professor; three years later was made William H. Carmalt professor of surgery, the chair he held until his appointment in 1947 as first United States and Yale professor of surgery in oncology; in August, 1952, retired, after 33 years on the faculty of Yale, with the title of William H. Carmalt professor emeritus of surgery; he was honored by 21 surgeons over the nation in 1951 when a portrait of him was presented to Yale, and a fund created in his name for partial support of a surgical assistant resident each year; during World War II served as consultant to the U. S. Office of Scientific Research and Development; as a member of the research organization's committee on medical research on burns, was instrumental in the development of the pyruvic acid method of treating burns; member of the founders group of the American Board of Surgery; member of the House of Delegates of the American Medical Association 1934-1935; helped formulate the policies of both the Connecticut State Cancer Society and the Connecticut State Medical Society, which he served as president; served as president of the American Surgical Association and Association of the Yale Alumni in Medicine; member of the Society of Clinical Surgery, Society of Neurological Surgeons, Sigma Xi, New England Surgical Society, and the American Association for Thoracic Surgery; fellow of the American College of Surgeons; in May, 1950, was awarded the annual medal of the American Cancer Society; chief surgeon in the Grace New Haven Community Hospital and Dispensary, where he was a member of the doctors' advisory committee; consulting surgeon for the Connecticut Tuberculosis Commission; in 1931 Western Reserve University of Cleveland conferred on him the honorary degree of doctor of science; died suddenly, Aug. 23, aged 67.

Gibby, Herbert B. ⊕ Wilkes-Barre, Pa.; born in Princeton, N. J., Sept. 12, 1871; University of Pennsylvania Department of Medicine, Philadelphia, 1895; an Associate Fellow of the American Medical Association and member of its House of Delegates from 1914 to 1921, in 1934, 1935, 1938, and 1939; past president of the Luzerne County Medical Society and the Lehigh Valley Medical Association; fellow of the American College of Surgeons; affiliated with Wilkes-Barre General Hospital, where he founded the tumor clinic and was on the surgical staff; on the staffs of the Nesbitt Memorial Hospital in Kingston and the Mercy Hospital; for a term president of the Wilkes-Barre Kiwanis Club; died at his summer home in Pocono Lake Preserve Aug. 7, aged 81, of heart failure.

Gordon, Donald ⊕ New York City; born in 1879; Columbia University College of Physicians and Surgeons, New York, 1906; formerly on the faculty of his alma mater; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served in France during World War I; consulting surgeon at Flushing (N. Y.) Hospital and Dispensary and Tuxedo Memorial Hospital in Tuxedo Park; consulting surgeon, traumatic surgery, Beekman-Downtown Hospital; consulting surgeon at the Veterans Administration Regional Office, New York department of prosthetics since 1949; died in Buffalo (N. Y.) General Hospital Aug. 14, aged 73, of a head injury received when struck by an automobile, and terminal pneumonia.

Dudgeon, Howard Rush ⊕ Waco, Texas; born in Chamois, Mo., Nov. 21, 1873; University of Texas School of Medicine, Galveston, 1899; member of the House of Delegates of the American Medical Association from 1939 to 1941, in 1943, 1945, and 1949; past president of the Texas State Medical Association; a charter member and founder of the Texas Surgical Society; past president of the McLennan County and Galveston County Medical societies and of the Central Texas Medical Society; at one time on the faculty of his alma mater, for many years member and chairman of the city school board; served during World War I; affiliated with Providence and Hillcrest Memorial hospitals; died July 31, aged 79, of coronary occlusion.

Strickler, Cyrus Warren Sr. ⊕ Atlanta, Ga.; Atlanta Medical College, 1897; professor emeritus of clinical medicine at his alma mater, now known as the Emory University School of Medicine; specialist certified by the American Board of Internal Medicine; member of the Endocrine Society; fellow of the American College of Physicians; served during World War I; affiliated with St. Joseph's Infirmary, Crawford W. Long Memorial Hospital, Piedmont Hospital, Grady Memorial Hospital, and the Emory University Hospital, where he died July 23, aged 79, of pulmonary emphysema and uremia.

Baily, Howard Houghton ⊕ Colonel, U. S. Army, San Antonio, Texas; University of Virginia Department of Medicine, Charlottesville, 1897; fellow of the American College of Surgeons; member of the Association of Military Surgeons of the United States; veteran of the Spanish-American War and World War I; entered the medical corps of the U. S. Army in 1904; rose through the various ranks to that of colonel in July, 1930; retired March 31, 1932, at his own request; died in Brooke Army Hospital, Fort Sam Houston, July 23, aged 79, of bilateral bronchopneumonia and arteriosclerosis.

Buckley, Charles Frederick, Edgewater, N. J.; Columbia University College of Physicians and Surgeons, New York, 1898; since 1914 police surgeon, fire department surgeon, and medical inspector of the schools of Edgewater; plant physician for the Aluminum Corporation of America, Corn Products Refining Company, Public Service Coordinated Transport, the Electric Ferries, Valvoline Oil Company, Cooper Dye Works, and various other industries in and around Edgewater; for many years on the staff of the Methodist Episcopal Hospital in Brooklyn; died Aug. 7, aged 80.

Harvey, Clifford Dawes ⊕ Brookline, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1910; formerly associate professor of surgery at Boston University School of Medicine; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; affiliated with Massachusetts Memorial Hospitals in Boston, Leonard Morse Hospital in Natick, Westboro (Mass.) State Hospital, Morrison Hospital, Whitefield, N. H., and Huggins Hospital in Wolfeboro, N. H.; died in Boston April 22, aged 73.

Albrecht, Mordecai, New York City; Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1934; for many years practiced in Charleston, W. Va.; died in Roosevelt Hospital April 19, aged 55, of acute myocardial infarction.

Behrens, Alvin ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1929; member of the American Academy of Ophthalmology and Otolaryngology;

⊕ Indicates Member of the American Medical Association.

specialist certified by the American Board of Ophthalmology; affiliated with Brooklyn Eye and Ear Hospital; died Aug. 3, aged 48, of multiple myeloma.

Blackwood, James Magee ⊕ New Castle, Pa.; Jefferson Medical College of Philadelphia, 1902; specialist certified by the American Board of Ophthalmology; fellow of the American College of Surgeons; served during World War I; affiliated with Jameson Memorial Hospital and the New Castle Hospital; died June 25, aged 76, of carcinoma of the liver.

Broadwin, Isra Tobias ⊕ New York City; University and Bellevue Hospital Medical College, New York, 1917; member of the American Psychoanalytic Association, American Psychiatric Association, and the American Orthopsychiatric Association; served as psychiatrist in chief of the Jewish Board of Guardians; affiliated with Montefiore, Bellevue, Mount Sinai, Hillside, and Lebanon hospitals; died in London, England, Aug. 5, aged 60, while attending the International Psycho-Analytical Congress.

Cogswell, George Proctor ⊕ Cambridge, Mass.; Harvard Medical School, Boston, 1893; on the staff of the Mount Auburn Hospital; died July 14, aged 86, of coronary thrombosis.

Coy, Warren Deweese ⊕ Youngstown, Ohio; Eclectic Medical College, Cincinnati, 1897; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; fellow of the American College of Surgeons; past president of the Mahoning County Medical Society; died in the Northside Unit of the Youngstown Hospital July 16, aged 81, of cerebral hemorrhage.

Deicher, Henry F. ⊕ Plymouth, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; died June 5, aged 80, of carcinoma of the liver.

Dixon, Winfield Scott ⊕ Metropolis, Ill.; Kentucky School of Medicine, Louisville, 1893; died May 23, aged 83.

Dwyer, Patrick James ⊕ Waterbury, Conn.; New York University Medical College, New York, 1897; formerly police and fire surgeon; on the honorary staff of St. Mary's Hospital, where he was on the staff for many years and where he died July 19, aged 80, of hypertrophy of the prostate and arteriosclerotic heart disease.

Edler, Robert Karl, Baltimore, Ohio; Ohio State University College of Medicine, Columbus, 1932; member of the American Society of Anesthesiologists; affiliated with Grant Hospital in Columbus and Lancaster-Fairfield Hospital in Lancaster; died in Peoria, Ill., June 1, aged 55, of cirrhosis of the liver and mitral insufficiency.

Elmer, Matthew K., Bridgeton, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1885; on the staff of the Bridgeton Hospital; formerly city physician; died Aug. 11, aged 93.

Fortney, Frank Dennis, Beckley, W. Va.; Baltimore Medical College, 1904; on the staff of the Pinecrest Sanitarium; died July 30, aged 80, of cerebral hemorrhage.

Franklin, William Essex, Pleasantville, N. J.; Cleveland Homeopathic Medical College, 1909; for many years practiced in Pittsburgh; died July 13, aged 70, of cardiorenal vascular disease.

Gallagher, Patrick Joseph ⊕ Seattle; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; medical director of the New World Life Insurance Company; while practicing in Spokane served as president of the Spokane County Medical Society; died in Providence Hospital July 12, aged 73, of carcinoma of the stomach.

Gibb, Alice Stearns ⊕ Elizabeth, N. J.; Cornell University Medical College, New York, 1924; affiliated with Elizabeth General Hospital; died in New York Hospital Aug. 2, aged 56, of carcinomatosis.

Goodrich, William Ray ⊕ Bluford, Ill.; College of Medicine and Surgery, Chicago, 1906; for many years surgeon for the Illinois Central Railroad; affiliated with the Jefferson Memorial Hospital in Mount Vernon, where he died July 15, aged 73, of coronary occlusion.

Griffin, Richard W. ⊕ Tiptonville, Tenn.; Medical Department of Tulane University of Louisiana, New Orleans, 1894; died in the Baptist Hospital, Memphis, July 23, aged 81, of cerebral thrombosis.

Hall, Lynn Thompson ⊕ Omaha; Drake University College of Medicine, Des Moines, 1911; professor of clinical medicine at University of Nebraska College of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the attending staff, University of Nebraska, Nebraska Methodist, Bishop Clarkson Memorial, and Lutheran hospitals; died July 10, aged 66, of cerebral hemorrhage.

Hanson, Albert N. ⊕ Santa Monica, Calif.; College of Physicians and Surgeons, Baltimore, 1908; member of the Utah State Medical Association; for many years practiced in Salt Lake City; died July 18, aged 82, of angina pectoris and diabetes mellitus.

Hess, H. Lewis ⊕ Kansas City, Mo.; University Medical College of Kansas City, Mo., 1909; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; affiliated with St. Joseph's and Kansas City General hospitals; died July 29, aged 71, of cerebral thrombosis.

Horn, Isaah Buford, Washington, D. C.; Howard University College of Medicine, Washington, 1926; died July 22, aged 54.

Hunte, August Frederick ⊕ Alhambra, Calif.; Rush Medical College, Chicago, 1899; member of the Minnesota State Medical Association; formerly associated with the Indian Service; died in Garfield Hospital, Monterey Park, July 5, aged 82, of chronic myocarditis and hypertension.

Johnson, Karl Osborn ⊕ Bakersfield, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1942; member of the American Academy of General Practice; died in the Bakersfield Hospital Aug. 3, aged 41, of carcinoma of the testicle.

Johnson, Lee T., Dallas, Texas; University of Louisville (Ky.) Medical Department, 1905; died July 6, aged 70.

Joseph, Walter Max, Cleveland; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1921; died June 26, aged 56, of glioma.

Keeler, Harold Raudenbush ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1921; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Physicians; affiliated with Methodist Episcopal Hospital, where he died Aug. 19, aged 59, of carcinoma of the pancreas.

Kelley, John Thomas Jr. ⊕ Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1890; an Associate Fellow of the American Medical Association; professor of gynecology emeritus at Georgetown University School of Medicine; fellow of the American College of Surgeons; on the staff of the Providence Hospital; died July 30, aged 89, of cerebral thrombosis and arteriosclerosis.

Kellum, Monford Romain ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1901; on the staff of Lutheran Hospital; died July 20, aged 75, of coronary embolism.

Loeser, Wilhelm, Oklahoma City, Okla.; Northwestern University Medical School, Chicago, 1905; died July 10, aged 76, of hypostatic pneumonia.

Longmire, Victor Melton ⊕ Temple, Texas; University of Louisville (Ky.) Medical Department, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served during World War I; on the staff of the Scott and White Memorial Hospitals; died July 27, aged 63, of myocardial infarction and arteriosclerosis.

Lucas, Wilbur Wayne ⊕ Tiffin, Ohio; Starling Medical College, Columbus, 1904; member of the American Academy of General Practice; affiliated with Mercy Hospital; died July 18, aged 72, of coronary thrombosis.

McCormick, Roscoe Conklin, Colorado Springs, Colo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; affiliated with Union Printers Home and Tuberculosis Sanatorium; died in Memorial Hospital June 30, aged 75, of myocardial infarction and coronary occlusion.

Macklin, Walter Fullarton ⊕ Lieut. Col., U. S. Army, retired, Tampa, Fla.; Columbia University College of Physicians and Surgeons, New York, 1898; fellow of the American College of Surgeons; served during World War I; entered the medical corps of the U. S. Army on July 1, 1920; promoted to lieutenant colonel in 1937 and retired April 30, 1939; at one time on the staff of Flushing (N. Y.) Hospital; died recently, aged 78, of cirrhosis of the liver.

Madara, Joseph Edward ⊕ St. Marys, Pa.; Medico-Chirurgical College of Philadelphia, 1911; during World War I commissioned a captain in the U. S. Army and was sent to Camp Las Casas, Puerto Rico, as camp sanitary inspector; died July 25, aged 71, of coronary thrombosis.

Merideth, Clyde O. Jr. ⊕ Emporia, Kan.; University of Kansas School of Medicine, Kansas City, 1931; president of the Lyon County Medical Society; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; on the staff of the Newman Memorial County Hospital and St. Mary's Hospital; died July 26, aged 47, of carcinoma of the lung with metastasis.

Minahan, Patrick Robert ⊕ Green Bay, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; served as president of the State Medical Society of Wisconsin, Brown-Kewaunee Door Counties Medical Society, and Brown County Historical Society; captain in the medical corps of the U. S. Army during World War I; affiliated with Bellin Memorial, St. Mary's, and St. Vincent's hospitals; died July 20, aged 78, of arteriosclerosis and myocarditis.

Nathanson, Millicent E. Falck, San Francisco; University of California Medical School, San Francisco, 1893; died July 15, aged 81, of metastatic carcinoma.

Neville, William, McComb, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1901; president of the First National Bank and of the McColgan Building and Loan Association; died July 27, aged 74, of Hodgkin's disease and carcinoma of the colon.

Nichols, Harry ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1913; affiliated with Garfield Park Community Hospital, where he died Aug. 8, aged 71, of cardiac decompensation and diabetes mellitus.

Payne, John Edward ⊕ Arlington, Va.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922; staff member of the Arlington Hospital, where he died July 25, aged 55, of cerebral hemorrhage.

Pond, Erasmus Arlington ⊕ Brooklyn; University of Vermont College of Medicine, Burlington, 1889; Bellevue Hospital Medical College, New York, 1890; died in St. John's Hospital July 8, aged 84, of cerebral embolus.

Poole, Albinus ⊕ West Union, W. Va.; University of Maryland School of Medicine, Baltimore, 1900; served as president and secretary of the Doddridge County Medical Society; affiliated with St. Mary's Hospital, Clarksburg, and St. Joseph's Hospital, Parkersburg, where he died July 21, aged 84, of acute leukemia.

Pritchard, William Clarence, Philadelphia; Jefferson Medical College of Philadelphia, 1906; formerly professor of histology and anatomical embryology at Temple University School of Medicine and on the faculty of his alma mater; served on the staff of Temple University Hospital; died Aug. 3, aged 71, of coronary occlusion.

Purdy, Frederick Parsons, Mukwonago, Wis.; Baylor University College of Medicine, Dallas, Texas, 1917; served during World War I; on the staff of the Waukesha Memorial Hospital; died in Veterans Administration Hospital in Wood July 27, aged 61, of cardiac insufficiency.

Roberts, Samuel Tize ⊕ De Ridder, La.; University of the South Medical Department, Sewanee, Tenn., 1901; coroner of Beauregard parish; on the staff of the Beauregard Memorial Baptist Hospital; died July 14, aged 73, of cancer.

Schwatka, Charles Taylor ⊕ Crisfield, Md.; Baltimore University School of Medicine, 1904; died July 10, aged 69, of coronary disease and nephritis.

Seale, Ira Bolton ⊕ Holly Springs, Miss.; Memphis (Tenn.) Hospital Medical College, 1910; past president of the North Mississippi Medical Society; served on the state board of health; on the staff of the North Mississippi Hospital; for many years trustee of the Baptist Memorial Hospital in Memphis, Tenn., and the Blue Mountain (Miss.) College; died in the Mississippi Baptist Hospital, Jackson, Aug. 19, aged 73, of cerebral hemorrhage.

Shumaker, Howard Keller ⊕ Bellevue, Ohio; Starling Medical College, Columbus, 1894; for many years member and president of the board of education; chairman of the board of health of Bellevue; at one time a medical missionary in China; president and a member of the board of directors of the Union Bank; on the staff of Bellevue Hospital; died July 27, aged 81, of coronary thrombosis.

Smith, Bernard Fletcher, San Antonio, Texas; University of Texas School of Medicine, Galveston, 1906; served overseas during World War I; died in the Nix Memorial Hospital July 7, aged 71, of intestinal obstruction, tuberculosis, peritonitis, and gastric ulcer.

Sparks, Thomas Plewman Sr. ⊕ New Iberia, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1920; served during World War II; died July 11, aged 56.

Stahlman, Frederick C. ⊕ Indiana, Pa.; Western University of Pennsylvania Medical College, Pittsburgh, 1896; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; for many years a member and past president of the local school board; affiliated with Charleroi-Monessen Hospital in Charleroi, where he died July 15, aged 84, of a heart attack.

Tiernon, Luke Bart ⊕ St. Louis; St. Louis College of Physicians and Surgeons, 1909; formerly county coroner; member of the Industrial Medical Association; died July 27, aged 70, of cancer.

Watson, James Alexander ⊕ Springville, Ala.; Birmingham Medical College, 1903; past president of the St. Clair County Medical Society; died July 16, aged 78, of pneumonia.

White, Milo Ritter ⊕ Detroit; Johns Hopkins University School of Medicine, Baltimore, 1925; certified by the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; affiliated with the Henry Ford Hospital, where he died July 29, aged 58, of cerebral vascular accident.

Williams, Benjamin Gregory ⊕ Oskaloosa, Iowa; Barnes Medical College, St. Louis, 1902; died in St. Joseph's Hospital, Brainerd, Minn., Aug. 2, aged 78, of multiple cerebral thrombosis due to arteriosclerosis.

Winters, William Thomas, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; served on the staff of the Garfield Park Community Hospital; died July 26, aged 86, of heart disease.

Woolling, Richard H. ⊕ Pulaski, Va.; University College of Medicine, Richmond, 1896; company doctor for the Virginia Iron, Coal and Coke Company; assistant surgeon for the Norfolk and Western Railway Company; a director of the Pulaski National Bank for many years; from 1926 to 1948 on the staff of the Pulaski Hospital, where he died June 17, aged 81, of lymphatic leukemia.

Yocum, Boaz ⊕ Coal City, Ind.; Louisville (Ky.) Medical College, 1893; for many years county health officer; died in Union Hospital, Terre Haute, July 17, aged 85, of prostatitis.

FOREIGN LETTERS

DENMARK

Measures Against Poliomyelitis.—Recent legislation in Denmark reflects the growing recognition of the responsibility of the community for the victims of poliomyelitis. In the past when they have needed prolonged treatment and reeducation of paralyzed limbs, there have been means by which the expenses incurred could be shifted from the individual person to the community. But these means have hitherto been somewhat cumbersome and roundabout, with the result that applicants for financial support have often had to wait a long time for their cases to be acted on. Now, on the recommendation of the physician in charge of the treatment of such patients, the paralyzed patient can receive economic support for two years, in very special cases up to four years, while he is undergoing physical reeducation. He must, however, faithfully follow, the instructions given him by his physicians if he is to qualify for such economic support.

At a recent meeting of the Danish Pediatric Society, Dr. F. Neukirch showed how much can be done by highly specialized treatment in reducing the mortality from poliomyelitis. His material consisted of 2,900 cases, including about 1,000 paralytic patients treated at the Blegdam Hospital between July 7, 1952, and Feb. 8, 1953. There were 341 patients whose respiration or deglutition or both were interfered with so much that special treatment was required. Among the first 31 patients in this class, treated along hitherto conventional lines, as many as 27 died. This appalling mortality led to more radical treatment, started on Aug. 26, 1952, and hinged on cooperation between anesthesiologists and epidemiologists. The treatment consisted of early tracheotomy and the introduction into the trachea of a rubber tube fitted with an inflatable cuff, so devised that it fitted tightly to the wall of the trachea. The so-called to-and-fro system of manual ventilation was accomplished with the help of a rubber bag; the mixture of gas was usually oxygen and nitrogen in equal proportions. The respiratory tract was kept free from secretions by frequent aspiration with a catheter introduced into the tracheal tube. The mortality among the 310 patients treated in this way till Feb. 5, 1953, was reduced from 54% to 38% for the first 50 patients thus treated and to only 22% for the last 50 patients. This achievement went far to prove how much can be effected when great care is taken by the team of physicians and nurses engaged in such highly technical treatment.

Cures for Seasick Seamen.—For a seafaring people like the Danes, the motion sickness, which some men continue to experience in spite of years of seafaring, is a serious problem. It may be supposed that the advances made in the treatment of seasickness during World War II could successfully be used in chronic cases, but this is disproved by a recent systematic investigation by three Danish physicians, Harald Anthonisen, Erik Jacobsen, and Fritz Reymann. In conjunction with the Danish Seamen's Hygiene Committee, a firm of manufacturing chemists, seamen's organizations, and their respective publications, the physicians have circulated a questionnaire to seasick seamen. Their definition of a seasick seaman is a person who, after having been to sea for at least a year, still suffers from seasickness. Altogether 128 seamen and 6 women employed at sea undertook to answer the questionnaires and to participate in a scheme for testing various drugs with antihistamine properties. These drugs included diphenhydramine hydrochloride and dimenhydrinate (Dramamine, Neptusan, etc.).

The recipients of the tablets in question were not told the particular brand to which each consignment of tablets belonged, and when they applied for a new consignment, they were given a different brand and asked to state which of the two proved most effective. A statistical analysis of the information thus obtained failed to show any significant difference between the various brands with regard to their general effect, the time at which they proved effective, the dosage, the duration of their action, and the frequency of side-effects. The side-effect most likely to be troublesome was drowsiness, which, however harmless and even pleasant it may be for a passenger, is much more serious for a seaman when he is on duty. But it was noted that such drowsiness lasted, as a rule, only a short time and was seldom pronounced. In about 52% of all the patients, every sensation of seasickness disappeared, and, in about 27%, appreciable mitigation of symptoms was achieved. There remained 11% for whom some improvement could be claimed and another 11% for whom there was no benefit whatever. No significant difference in the effects of this treatment was demonstrable in connection with the age of these patients, who had been to sea from 1 to 25 years, nor was any new light thrown on the influence, if any, of a familial predisposition to seasickness.

LONDON

Eye Sanatorium.—The first sanatorium devoted to the treatment of ocular tuberculosis in Great Britain was opened in June, 1951. It is situated in Kent, organized by one of the London Regional Hospital Boards, staffed by members of the world-famous Moorfields group of ophthalmic hospitals, and available for the treatment of cases of ocular tuberculosis from all parts of the United Kingdom. Results of the first year operation of the sanatorium have just been reported by D. P. Choyce and A. G. Cross (*Brit. J. Ophth.* **37**:406, 1953). During the year 47 patients were treated and discharged, including 22 with proved or doubtful tuberculosis, 11 with proved or doubtful sarcoidosis, and 14 with nonspecific inflammation.

The general plan of treatment was that patients spent the first two weeks after admission resting in bed. Thereafter they got up for increasing periods until they were up all day except for a rest of one hour after meals. Streptomycin and *p*-aminosalicylic acid were given "where there was evidence to suggest the presence of Mycobacterium tuberculosis, tuberculin where the skin sensitivity was high and the ocular lesions had an appearance suggesting that it was due to hypersensitivity," and cortisone "in acute inflammatory lesions which appeared to be threatening corneal or lens transparency." The average length of stay was four months (range, two months to over a year). All but two patients gained weight, the average increase being 7 lb. (3.2 kg.).

The results of treatment, though the number of cases is too small to be of statistical value, are taken to "suggest that cases of tuberculosis respond well to treatment at the sanatorium, while cases of possible tuberculosis, sarcoidosis and possible sarcoidosis, and nonspecific cases, appear, generally, to improve at the sanatorium, but not in such a marked manner as the definite tuberculosis cases . . . In order to carry out its functions adequately, patients should be admitted to the Eye Sanatorium immediately upon the request of the surgeon in charge of the case. . . ."

The Teaching of General Practice.—The British Medical Students' Association has just published "A Survey of the General Practitioner Schemes in Operation in British Medical Schools." Of the 21 medical schools included in the survey, 9 provide training in general practice that is either officially recognized or organized. These schemes are divided into four categories: (1) health center schemes in centers operated by university authorities for teaching purposes; (2) residential schemes, in which the students spend some time living with the general practitioner, attending his surgery and accompanying him on his rounds; and (3) attachment schemes, in which the student works with a general practitioner only in the mornings for a

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

given period of time, usually two weeks, including in some cases evening surgery by arrangement with the general practitioner; and (4) day visit schemes, in which the student spends a day with a general practitioner.

Typical of the "attachment" scheme is that in force at University College Hospital, one of the first London teaching hospitals to adopt such a scheme. Thirteen general practitioners near London take students into their practices, usually for a week. The scheme is entirely voluntary, and is followed in the student's final year. The individual student chooses his practitioner and, in consultation with the medical school authorities, arranges to spend a week with him. As a rule the student lives with the practitioner or in a nearby boarding house. It is estimated that 60% of those eligible participate in the scheme.

Most elaborate of all is the scheme now in force in the University of Edinburgh. Attendance at a public dispensary for the indigent has been compulsory in the Edinburgh medical curriculum for over a century. Officially, it ceased to be compulsory when the National Health Service was introduced in 1948. It was retained, however, on a voluntary and modified basis. In 1952, the university decided to redevelop the scheme and make it compulsory as soon as facilities permitted participation of every student. For the development of the scheme the university last year received a generous grant of £25,000 from the Rockefeller Foundation. In October, 1952, a general practice teaching unit was created as a separate entity of the faculty of medicine. This unit consists of two general practices, with approximately 2,000 patients in each. Each practice is staffed by two physicians, one nurse, one almoner, and one secretary. In addition, there is a director of the unit and a trainee who is a recently qualified graduate appointed for one year. Twelve to 15 students are taken into each practice for an academic term of 10 weeks. Each student spends two afternoons a week attending the practice, but the actual amount of visiting that a student may undertake in addition is left for him to decide. One of the weekly sessions consists of a consulting session, when he is the only person present when the physician sees the patients who attend without an appointment. The student responsible for a patient or for a family visits them in their home, and at the end of his term he is expected to present a written case history, covering social as well as medical details, for discussion by the group.

Private Patients' Prescriptions.—As *Practitioner* (171:2 [July] 1953) points out, "One of the anomalies of the National Health Service for which no justification can be found is that whereby a taxpayer who wishes to obtain his general practice services privately must pay for any drugs or appliances prescribed for him, even though he does not lose his right to obtain his specialist services through the N. H. S." The further comment is made that "Why a patient should be compelled to pay for his medicines simply because he decides to pay his doctor for his professional advice is completely incomprehensible to the ordinary mind—except on political grounds. To deprive a patient of this assistance from the Service is as unjust as it would be to compel every citizen to make full use of the Service." This is a widely held view, and at the recent annual representative meeting of the British Medical Association at Cardiff a motion was passed asking for further reports on the matter to be made to the ministry. Repeated appeals have been made to the ministry but hitherto without any success. It was suggested at Cardiff, however, that there were some grounds for hoping that the ministry might now be prepared to give way on this point.

The Specter of Nationalization.—The following verbatim excerpt from the official report of the annual representative meeting of the British Medical Association at Cardiff in July speaks for itself: "Dr. . . . moved: That this meeting, representative of all branches of the profession, expresses its strong opposition to full-time salaried service, and reaffirms the resolution passed in May, 1946: The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as whole becoming full-time salaried servants of the State or local authorities."

The motion was carried unanimously, only one member failing to vote.

MEXICO

Study of 195 Children with Meningitis.—At the Hospital Infantil (Children's Hospital, Mexico, D. F.), during the period between January, 1951, and February, 1953, every patient with meningoencephalitic manifestations was carefully studied, and cultures of the spinal fluid were carried out. The total series comprised 621 cases. Most of the patients were less than one year old. The results of this investigation, which was undertaken by Drs. Olarte and Reyes, were published in the *Boletín del Hospital Infantil* (10:118, 1953). According to the authors a positive culture developed in 31% of the cases. This permitted classification of the meningitis as follows:

Tuberculous Meningitis.—This was the most frequent type (54.5%) in the group studied. It is not known whether this figure represents a true epidemiological incidence in this part of the country or whether the chronic course of the disease accounts for the greater number of cases seen at the hospital.

Purulent Meningitis.—The bacteria that predominated in this type of meningitis were, in order of frequency: Diplococcus pneumoniae (16.5%), Hemophilus influenzae (9.5%), and Salmonella types (3.0%). The relatively frequent finding of Salmonella meningitis can probably be explained by the high incidence of salmonellosis in Mexico.

Only two cases of Neisseria meningitidis were found. The mortality rate and morbidity of meningococcus meningitis in Mexico City are very low; no epidemic has occurred during recent years.

The remaining 14% of the cases were caused by the following organisms: three by Staphylococcus aureus, two by N. meningitidis, two by Pseudomonas aerurginosa, two by paracolon bacillus, two by Alcaligenes faecalis, two by Proteus mirabilis, two by Staph. albus, one by N. flava, one by Streptococcus pyogenes, one by Str. viridans, one by Escherichia coli, and one by diphteroides. In eight spinal fluids micro-organisms were isolated that could not be completely identified. In four cases, two types of organisms were found simultaneously, and in one case of tuberculous meningitis three different bacteria were isolated.

Effect of DDS on Nocardia Brasiliensis.—The results of the use of DDS (p,p'-sulfonyldianiline) as an active drug against several bacterial diseases, particularly lepromatous leprosy have been reported. The results include the use of DDS on Nocardia brasiliensis. The report refers to studies in vitro, to experimental infection in mice, and to eight cases of actinomycotic mycetoma caused by Nocardia.

Studies in vitro showed that DDS totally inhibited N. brasiliensis at a titer of 1:10,000 and partially inhibited growth at a titer of 1:50,000. Other nocardias studied (N. asteroides, N. madurae, and N. pelletieri), were not sensitive to DDS. The studies on experimental infection in mice with N. brasiliensis, inoculated intraperitoneally, showed only a slight effect of the drug. Infections graded from 1+ to 2+ were observed in the treated animals, as against infections classed as 4+ seen in the controls. The best results were seen in the animals receiving the smaller dose of the inoculum and longer therapy with the drug. No noticeable difference was seen with the different doses used: 100, 200, and 300 mg. per kilogram.

The results of the clinical studies, however, were very encouraging. The clinical course of the eight patients with actinomycotic mycetoma of N. brasiliensis origin averaged four years. In two, the lesions were localized in the soft tissues; in four, the lesions invaded bones and joints; and in two, thoracic and pulmonary invasion were found. Seven of the eight patients were cured after an average of two years of treatment with DDS, given in a dose of 100 mg. two times a day. In one patient with thoracopulmonary lesions, the drug did not have any effect. This patient had previously received sulfoxone (Diasone) sodium irregularly and in insufficient doses. It is concluded that to date DDS is the drug of choice for the treatment of actinomycotic mycetoma of N. brasiliensis origin, that it should be given in doses of 200 mg. daily, and that treatment should be sustained for many months after clinical symptoms have disappeared. Reduction of treatment may cause resistance on the part of the microorganism.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Hospitals in General: Criteria of Tax Exemption.—The plaintiff, Sutter Hospital of Sacramento, filed an action to recover real property taxes paid under protest for the fiscal year 1946-1947. The trial court found that the plaintiff did not meet certain conditions for exemption and, therefore, ruled in favor of the defendant. From this judgment the plaintiff hospital appealed to the Supreme Court of California.

In 1944, a constitutional amendment was adopted relating to the exemption of certain property used for hospital purposes. The relevant portions provide that the "Legislature may exempt from taxation all or any portion of property used exclusively for . . . hospital purposes and owned by . . . corporations organized and operated for . . . hospital . . . purposes, not conducted for profit and no part of the net earnings of which inures to the benefit of any private shareholder or individual." Unlike certain other provisions relating to tax exemptions, said the court, this amendment was not self-executing, and legislation was required in order to effect the exemption of any property. The amendment was purely permissive rather than mandatory in character, and it qualified section 1 of article XIII, which requires that all property be taxed according to its value "except as otherwise in this Constitution provided." In other words, the legislature could refrain from exempting any of the property referred to in the amendment, or it could exempt only such property as might meet the conditions specified in the amendment and such further conditions as the legislature might see fit to impose. The legislature followed the latter course, continued the Supreme Court, and enacted section 214 of the Revenue and Taxation Code, which imposes conditions in addition to those found in the constitutional amendment and provides that "Property used exclusively for . . . hospital . . . purposes owned and operated by . . . corporations organized and operated for . . . hospital . . . purposes is exempt from taxation if: (1) The owner is not organized or operated for profit; (2) No part of the net earnings of the owner inures to the benefit of any private shareholder or individual; (3) The property is not used or operated by the owner or by any other person for profit regardless of the purposes to which the profit is devoted; . . ."

The plaintiff was organized as a nonprofit corporation in 1935. It acquired the physical assets of its predecessor by giving in exchange its bonds. In 1945, plaintiff's physical assets for accounting purposes had a value of $764,895.39, and its then bonded indebtedness was some $292,000. For 1945, the surplus of income over current expenses, which included interest payments and depreciation on the buildings, machinery, and equipment, amounted to $86,609.24; for 1946, the surplus was $106,603.12. Reduced to percentages, the surplus for each year was slightly in excess of 8% of gross income. The surplus was mingled with other cash on hand and was used for debt retirement and for expansion, such as, for instance, the building and equipping of an x-ray room in 1947 at a cost of $60,000.

It is conceded that the plaintiff operated its hospital properties with the intent of producing, if possible, a surplus of income over expenses so as to permit the periodic retirement of a portion of its bonded indebtedness and to permit the expansion of its facilities. It is further conceded that it had succeeded and was succeeding in accomplishing this purpose. The defendant argues, therefore, that by reason of the plaintiff's profit-making intent and purpose, the allowance of the claimed exemption would run counter to the statutory condition that such property be "not used or operated by the owner . . . for profit regardless of the purposes to which the profit is devoted."

In relation to tax laws, the phrase "conducted for profit," which appears to be the equivalent of "operated for profit," has presented some difficulty but has been generally held to convey the meaning of operated or conducted for the purpose of making a profit. Accordingly, the test indicated by such phrases, as so construed, is not necessarily whether there is or may be a profit, but whether the claimant is operated or conducted for the purpose of making a profit; that is, whether the charges are fixed with the intention of yielding a surplus over and above operating expenses.

It appears that, at the time section 214 of the Revenue and Taxation Code was enacted in 1945, the meaning of the word "profit," as used in tax exemption laws, had been construed in such manner that the nonprofit requirements were deemed to be satisfied so long as none of the "net earnings" accrued "directly or indirectly to the stockholders or members of the association" or so long as no part of the "net income inures to the benefit of any private person." In other words, the Supreme Court continued, the profit concept had been defined in terms relating solely to the purpose for which "net income" or "net earnings" might be used and only the use thereof for the purpose of benefiting a private person was prohibited. In the light of these prior definitions, judicial and legislative, we turn now to a consideration of the terms employed in the first three subdivisions of section 214 of the Revenue and Taxation Code. These subdivisions contain separately stated but interrelated conditions. Property used exclusively for hospital purposes is thereby declared exempt only "if: (1) The *owner is not organized or operated for profit;* (2) No part of the *net earnings* of the owner inures to the benefit of any private shareholder or individual; (3) The property is *not used or operated* by the owner or by any other person *for profit regardless of the purposes to which the profit is devoted*; . . ." If subdivision 3 had been omitted, it might well be argued that the legislature intended that the nonprofit conditions of subdivision 1 would be satisfied so long as none of the "net earnings" inured to the benefit of any private person. But subdivision 3 cannot be declared to have been inserted without reason, and it seems clear that it was intended thereby to broaden the profit concept so as to deny exemption whenever the property is operated for the purpose of profit "regardless of the purposes to which the profit is devoted." Thus, said the court, it appears that the legislature adopted a different concept of "profit" for the purposes of section 214 by providing that the nonprofit requirements could not be satisfied merely by devoting the net earnings to exempt (hospital) purposes. In any event, the most that can be said is that there is grave doubt as to whether the legislature intended that the property used as is plaintiff's property, by an owner operating for the admitted purpose of producing net earnings, was intended to be accorded the exemption.

Whether the accrual of "net earnings" will defeat the right to the exemption depends on the particular facts involved. Here the determinative factor is the operation of plaintiff's property for the admitted purpose of producing a profit in the sense that the operation was one deliberately designed to produce income in excess of all operating costs. The fact that plaintiff has succeeded in producing net earnings is not accidental or allocable to a fortuitous error in judgment in determining the charges made for its services. On the contrary, plaintiff functioned on a sound financial basis in a manner akin to any modern commercial enterprise intent on producing a profit from its operations. The plaintiff argued that the above indicated construction of the welfare exemption, denying exemption because of the adoption of sound financial practices, will make it difficult, if not impossible, for modern hospitals to plan for expansion and the improvement of facilities for the better service of the public without losing the benefit of the exemption. This argument may merit serious consideration, but it should be addressed to the legislature rather than to the courts. This court's function begins and ends with construing the statute as enacted. The present form of the statute compels the conclusion that plaintiff's claim for exemption must be denied because of its failure to meet the condition that its property be "not used or operated . . . for profit regardless of the purposes to which the profit is devoted."

Accordingly the judgment of the trial court in favor of the defendant and against the hospital was affirmed. *Sutter Hospital of Sacramento v. City of Sacramento, 244 P. (2d) 390 (California 1952).*

Pattern of Functional Recovery in Acute Renal Failure.—Study of a child in whom a so-called ischemuric episode, or episode of renal ischemia resulting in ischuria, developed after the ingestion of mercuric chloride showed that the return of renal function, which was fairly complete, followed a distinct pattern. Function was recovered first in the glomeruli, then in the proximal portions of the nephron, and finally in the distal segments. The close correlation between this sequence of events and the structural path of healing suggested by a knowledge of the changes produced in the nephrons during acute renal failure indicates that recovery from renal failure due to other causes may follow the pattern observed in this case. Fluid replacement therapy during the initial stages of diuresis should be guided by a knowledge of the composition of the fluid being lost. This fluid may be identical with an ultrafiltrate of plasma (virtually extracellular fluid); it should, therefore, be replaced with isotonic sodium chloride solution or solutions similar in composition to extracellular fluid, such as Ringer's solution. The kidneys possess little or no ability to excrete or retain solutes selectively and this makes it advisable to give the replacement fluid intravenously, thus avoiding modification of the solution by the bowel wall. The difficulties of replacement therapy diminish as renal function returns; if the water and electrolytes given are adequate in quantity, the composition of the body fluids will be kept constant.

Prophylactic Use of Sulfonamides and Penicillin in Rheumatic Fever.—Rheumatic fever recurred in only two of a group of 467 hospitalized children receiving prophylactic treatment with sulfonamides for from three months to two years over a 10-year period. These figures may be compared with 9 recurrences in a group of 44 controls, or 38 recurrences in a group of 154 children observed in a two-year period prior to the institution of the sulfonamide regimen. Toxic reactions, especially frequent with sulfanilamide, necessitated the discontinuance of sulfonamide therapy in 34 other children. Investigation of recurrences in children discharged from the hospital with the expectation that they would be kept on the sulfonamide regimen under the care of their own physicians or a clinic showed that in each case recurrence was preceded by discontinuance of sulfonamides. Fifteen of the children with recurrences were readmitted to the hospital; they were found to have stopped taking the drug from three months to two years (average, seven months) earlier. The high incidence of untoward reactions to the sulfonamides led to their replacement with crystalline penicillin G given orally. Tolerance for this product was perfect and during the period from May, 1950, to July 1, 1952, there were no recurrences of rheumatic fever in any of the 102 patients receiving it. One patient, who was discharged from the hospital completely free of activity, was readmitted a little more than two months later with a fulminating recurrence; inquiry showed that his parents had failed to give him penicillin after the two weeks' supply given to them on his discharge was exhausted. These figures show that both the sulfonamides and penicillin, when given continuously, can prevent the recurrence of rheumatic activity; penicillin, however, has the great advantage of not causing toxic reactions.

Hemolytic Disease of the Newborn Due to ABO Incompatibility.—Hematological and serological investigations furnished strong evidence that ABO incompatibility was responsible for neonatal hemolytic disease in binovular twins, in one of whom kernicterus resulted in death, while the other made a full recovery. The mother was a healthy Rh-positive primigravida, aged 25, who had never received any transfusions or injections of blood or serum. She had twin cousins and twin uncles and was herself a twin. Tests showed that the only demonstrable antibody which could have played a part in the hemolytic disease of the infants was her anti-B; β-agglutinin was found in her serum in high titer, rising to a maximum of 32,000 on the 22nd day after delivery. Her marked isoimmunization was also indicated by the presence of immune anti-B agglutinins and hemolysins. Maternal ABO isoimmunization occurs in a considerable proportion of normal pregnancies without injury to the infant; before attributing erythroblastosis fetalis to anti-A or anti-B, other possible incompatibilities should be thoroughly excluded and some evidence of the presence, or preferably action, of harmful maternal antibodies in the infant should be obtained. Diagnosis in the case of these twins was made too late for any effective treatment to be undertaken; the less severely affected twin recovered without specific treatment. Initial asphyxia and greater immaturity may have contributed to the development of kernicterus in the twin who died. The possibility of ABO incompatibility should be kept in mind, especially when an Rh-positive mother has previously given birth to infants affected by erythroblastosis or icterus praecox and possibly also when there is a history of unexplained abortions.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

ultimately died. The six fatal cases represent all the deaths in some 1,500 cases of hepatitis admitted during the period of this investigation. Five of the 11 patients were moderately to severely ill and 6 had a fulminant course with coma. In the first group, hormone therapy resulted in a symptomatic control and a drop in serum bilirubin, but in three of these relapses occurred. One patient had multiple relapses. No significant benefits were seen from hormonal therapy in the second group, and all six patients died. This is the third of three papers dealing with the use of adrenal hormones in viral hepatitis. The effect of these hormones on the clinical course and manifestations of viral hepatitis has been at times as striking as the results reported in rheumatic fever and rheumatoid arthritis. Unlike these diseases, however, hepatitis is usually a benign and self-limited disease followed by immunity. The high relapse rate attending corticotropin and cortisone therapy in hepatitis may reflect interference in immunity mechanisms. For this reason the routine use of hormone therapy in viral hepatitis does not seem indicated.

Renal Disease with the Salt Losing Syndrome.—Murphy and his associates point out that the term "salt losing nephritis" was introduced by Thorn and associates, when they described renal failure that simulated cortical insufficiency. They found that, in addition to the hypochloremia and dehydration without edema, there was present a shock-like state simulating acute adrenal insufficiency. Their report of two cases was followed by others presenting a total of eight cases. Murphy and associates report four additional patients with renal disease who exhibited the salt losing syndrome. The first patient had chronic renal disease that developed insidiously and was diagnosed as chronic glomerulonephritis. There were dehydration, low blood pressure, polyuria with small quantities of albumin, a low specific gravity and no casts. Weakness, pain in the legs, mental confusion, and vascular collapse disappeared along with other features of hypochloremia following intravenous injections of salt solution and sodium lactate. In the second patient, a diagnosis of extrarenal uremia and alkalosis was made because of excessive intake of alkalies and the elevated carbon dioxide combining power of the plasma. The disorder was later recognized as the salt depletion syndrome, and suitable treatment was followed by improvement. The third patient, in addition to the salt losing syndrome, had myocardial insufficiency and hypertension, as well as complications of chronic nephritis. Unfortunately, treating the salt losing syndrome by the infusion of a 3% sodium chloride solution resulted in acute pulmonary edema and death. Case 4 illustrates that the salt losing nephritis may develop during acute renal disease and that the process in the tubular apparatus may be reversible. The authors feel that the salt losing syndrome should be suspected in all cases of chronic renal insufficiency with impending uremia, particularly in these days when restriction of salt has become so popular in the treatment of nephritis, edema, heart disease and hypertension. Early recognition and adequate treatment may add years to the life of these patients.

Pulmonary Paragonimiasis.—Pulmonary paragonimiasis is a disease caused by the presence within the lung parenchyma of the oriental lung fluke, Paragonimus westermani. It is designated also as endemic hemoptysis, lung distoma and pulmonary distomiasis. Geographical distribution of the disease in man has been limited mainly to the Philippines, Japan, Korea and Formosa, and to some parts of China, India, South America, Africa, Nigeria, Thailand and the Malay States. Patients with this disease observed in the United States all had been in these endemic regions. The disease is benign. Korean and Filipino patients may at first become alarmed about the hemoptysis, but later become so accustomed to occasional blood spitting that they attach little significance to it. Some patients never seek medical aid, and the diagnosis is made incidentally while investigating some unrelated complaint. Although pulmonary lesions constitute the primary pathological process, involvement of virtually every organ system in the body has been recorded. Various drugs have been tried in the treatment of paragonimiasis, notably tartar emetic, emetine, iodized oil (Lipiodol) and azosulfamide (Prontosil). Several antimony compounds, arsenicals and methylene violet have been found ineffective in infected dogs. Because Fuadin was efficacious in the treatment of another fluke-induced disease, schistosomiasis, it was tried in paragonimiasis. Results have been encouraging but inconclusive. In cases observed in Korea, the authors resorted to the intermittent administration of emetine, and obtained symptomatic improvement. Paragonimiasis is usually contracted by the ingestion of raw or poorly cooked fresh water crustaceans such as crabs and crayfish. Pulmonary paragonimiasis will usually be manifested by the triad: hemoptysis, roentgenographic changes in the chest, and operculated Paragonimus ova in the sputum. The clinical evolution of paragonimiasis is characterized by chronicity and surprising benignity in spite of the persistently recurrent hemoptysis and x-ray findings. The roentgenographic findings in pulmonary paragonimiasis closely mimic those of pulmonary tuberculosis.

The kidneys possess little or no ability to excrete or retain solutes selectively and this makes it advisable to give the replacement fluid intravenously, thus avoiding modification of the solution by the bowel wall. The difficulties of replacement therapy diminish as renal function returns; if the water and electrolytes given are adequate in quantity, the composition of the body fluids will be kept constant.

Prophylactic Use of Sulfonamides and Penicillin in Rheumatic Fever.—Rheumatic fever recurred in only two of a group of 467 hospitalized children receiving prophylactic treatment with sulfonamides for from three months to two years over a 10-year period. These figures may be compared with 9 recurrences in a group of 44 controls, or 38 recurrences in a group of 154 children observed in a two-year period prior to the institution of the sulfonamide regimen. Toxic reactions, especially frequent with sulfanilamide, necessitated the discontinuance of sulfonamide therapy in 34 other children. Investigation of recurrences in children discharged from the hospital with the expectation that they would be kept on the sulfonamide regimen under the care of their own physicians or a clinic showed that in each case recurrence was preceded by discontinuance of sulfonamides. Fifteen of the children with recurrences were readmitted to the hospital; they were found to have stopped taking the drug from three months to two years (average, seven months) earlier. The high incidence of untoward reactions to the sulfonamides led to their replacement with crystalline penicillin G given orally. Tolerance for this product was perfect and during the period from May, 1950, to July 1, 1952, there were no recurrences of rheumatic fever in any of the 102 patients receiving it. One patient, who was discharged from the hospital completely free of activity, was readmitted a little more than two months later with a fulminating recurrence; inquiry showed that his parents had failed to give him penicillin after the two weeks' supply given to them on his discharge was exhausted. These figures show that both the sulfonamides and penicillin, when given continuously, can prevent the recurrence of rheumatic activity; penicillin, however, has the great advantage of not causing toxic reactions.

Hemolytic Disease of the Newborn Due to ABO Incompatibility.—Hematological and serological investigations furnished strong evidence that ABO incompatibility was responsible for neonatal hemolytic disease in binovular twins, in one of whom kernicterus resulted in death, while the other made a full recovery. The mother was a healthy Rh-positive primigravida, aged 25, who had never received any transfusions or injections of blood or serum. She had twin cousins and twin uncles and was herself a twin. Tests showed that the only demonstrable antibody which could have played a part in the hemolytic disease of the infants was her anti-B; β-agglutinin was found in her serum in high titer, rising to a maximum of 32,000 on the 22nd day after delivery. Her marked isoimmunization was also indicated by the presence of immune anti-B agglutinins and hemolysins. Maternal ABO isoimmunization occurs in a considerable proportion of normal pregnancies without injury to the infant; before attributing erythroblastosis fetalis to anti-A or anti-B, other possible incompatibilities should be thoroughly excluded and some evidence of the presence, or preferably action, of harmful maternal antibodies in the infant should be obtained. Diagnosis in the case of these twins was made too late for any effective treatment to be undertaken; the less severely affected twin recovered without specific treatment. Initial asphyxia and greater immaturity may have contributed to the development of kernicterus in the twin who died. The possibility of ABO incompatibility should be kept in mind, especially when an Rh-positive mother has previously given birth to infants affected by erythroblastosis or icterus praecox and possibly also when there is a history of unexplained abortions.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

ultimately died. The six fatal cases represent all the deaths in some 1,500 cases of hepatitis admitted during the period of this investigation. Five of the 11 patients were moderately to severely ill and 6 had a fulminant course with coma. In the first group, hormone therapy resulted in a symptomatic control and a drop in serum bilirubin, but in three of these relapses occurred. One patient had multiple relapses. No significant benefits were seen from hormonal therapy in the second group, and all six patients died. This is the third of three papers dealing with the use of adrenal hormones in viral hepatitis. The effect of these hormones on the clinical course and manifestations of viral hepatitis has been at times as striking as the results reported in rheumatic fever and rheumatoid arthritis. Unlike these diseases, however, hepatitis is usually a benign and self-limited disease followed by immunity. The high relapse rate attending corticotropin and cortisone therapy in hepatitis may reflect interference in immunity mechanisms. For this reason the routine use of hormone therapy in viral hepatitis does not seem indicated.

Renal Disease with the Salt Losing Syndrome.—Murphy and his associates point out that the term "salt losing nephritis" was introduced by Thorn and associates, when they described renal failure that simulated cortical insufficiency. They found that, in addition to the hypochloremia and dehydration without edema, there was present a shock-like state simulating acute adrenal insufficiency. Their report of two cases was followed by others presenting a total of eight cases. Murphy and associates report four additional patients with renal disease who exhibited the salt losing syndrome. The first patient had chronic renal disease that developed insidiously and was diagnosed as chronic glomerulonephritis. There were dehydration, low blood pressure, polyuria with small quantities of albumin, a low specific gravity and no casts. Weakness, pain in the legs, mental confusion, and vascular collapse disappeared along with other features of hypochloremia following intravenous injections of salt solution and sodium lactate. In the second patient, a diagnosis of extrarenal uremia and alkalosis was made because of excessive intake of alkalies and the elevated carbon dioxide combining power of the plasma. The disorder was later recognized as the salt depletion syndrome, and suitable treatment was followed by improvement. The third patient, in addition to the salt losing syndrome, had myocardial insufficiency and hypertension, as well as complications of chronic nephritis. Unfortunately, treating the salt losing syndrome by the infusion of a 3% sodium chloride solution resulted in acute pulmonary edema and death. Case 4 illustrates that the salt losing nephritis may develop during acute renal disease and that the process in the tubular apparatus may be reversible. The authors feel that the salt losing syndrome should be suspected in all cases of chronic renal insufficiency with impending uremia, particularly in these days when restriction of salt has become so popular in the treatment of nephritis, edema, heart disease and hypertension. Early recognition and adequate treatment may add years to the life of these patients.

Pulmonary Paragonimiasis.—Pulmonary paragonimiasis is a disease caused by the presence within the lung parenchyma of the oriental lung fluke, Paragonimus westermani. It is designated also as endemic hemoptysis, lung distoma and pulmonary distomiasis. Geographical distribution of the disease in man has been limited mainly to the Philippines, Japan, Korea and Formosa, and to some parts of China, India, South America, Africa, Nigeria, Thailand and the Malay States. Patients with this disease observed in the United States all had been in these endemic regions. The disease is benign. Korean and Filipino patients may at first become alarmed about the hemoptysis, but later become so accustomed to occasional blood spitting that they attach little significance to it. Some patients never seek medical aid, and the diagnosis is made incidentally while investigating some unrelated complaint. Although pulmonary lesions constitute the primary pathological process, involvement of virtually every organ system in the body has been recorded. Various drugs have been tried in the treatment of paragonimiasis, notably tartar emetic, emetine, iodized oil (Lipiodol) and azosulfamide (Prontosil). Several antimony compounds, arsenicals and methylene violet have been found ineffective in infected dogs. Because Fuadin was efficacious in the treatment of another fluke-induced disease, schistosomiasis, it was tried in paragonimiasis. Results have been encouraging but inconclusive. In cases observed in Korea, the authors resorted to the intermittent administration of emetine, and obtained symptomatic improvement. Paragonimiasis is usually contracted by the ingestion of raw or poorly cooked fresh water crustaceans such as crabs and crayfish. Pulmonary paragonimiasis will usually be manifested by the triad: hemoptysis, roentgenographic changes in the chest, and operculated Paragonimus ova in the sputum. The clinical evolution of paragonimiasis is characterized by chronicity and surprising benignity in spite of the persistently recurrent hemoptysis and x-ray findings. The roentgenographic findings in pulmonary paragonimiasis closely mimic those of pulmonary tuberculosis.

*Supply of Oxygen to Prematures and Appearance of Retrolental Fibroplasia. A. Huggert.—p. 147.

Administration of Oxygen and Retrolental Fibroplasia.—Huggert, in a previous paper, reported observations on the eyegrounds of 66 prematurely born infants with a birth weight of less than 2,600 gm. In many of these the fundus showed peripheral edema and changes in the caliber of the vessels, and more than 25% exhibited the picture similar to that regarded as the early stage of retrolental fibroplasia. Huggert reports further observations on 130 cases. The retinal vessels were often very narrow during the administration of oxygen, and vascular dilatation and peripheral edema occurred in most cases when oxygen was stopped, but in some instances even during the administration of oxygen. In the infants who had not been given oxygen, dilatation of the vessels and edema occurred immediately after birth. Retrolental fibroplasia developed in two of those who were treated with oxygen. Recently one of the infants in Huggert's clinic showed such severe retinal changes of early retrolental fibroplasia type that the infant was replaced in an incubator and was treated with oxygen. Under the oxygen treatment (with approximately 60% oxygen) there was a reversion of the retinal changes such as was reported by Szewczyk. Later, when the oxygen was gradually reduced, there was a reappearance of the vascular dilatation in one of the eyes which lasted for about a week and then disappeared. This case has been observed too recently for final evaluation. As further proof of a connection between oxygen therapy and retrolental fibroplasia the author points out that the latter was rarely if ever observed before 1941, when it was noted in an increasing number of prematurely born infants in the United States. In Sweden it began to be observed more frequently in 1944 and 1945. Incubators with special oxygen administration began to be generally used in the United States about 1940 and in Sweden in 1944. The incubators used in Sweden usually supply 45% oxygen, whereas many of the models used in the United States supply between 60 and 80% oxygen. If the oxygen content as such, or the rapid change-over from a high oxygen content to a normal one, is the decisive factor in retrolental fibroplasia, the stress involved in the change will be severer in the American type incubators with their more concentrated oxygen supply.

have lain only in an orthopneic position should not be made to lie horizontally on the operative table. These patients were placed at a 35 to 45 degree angle and the plane of the table was slightly rotated to the left. A dose of 0.05 gm. of Etamyl (5,5-isoamylethylbarbiturate) or pentobarbital (Nembutal) was given to the patients three hours before the operation and again one hour later, then 1 cg. of morphine with 0.5 mg. of atropine was given one hour before the operation. Anesthesia was accomplished with thiopental (Pentothal) sodium, curare, procaine and ether. Only one patient died during the operation, but she had been placed in a position which was more horizontal than her usual position and death was ascribed to this fact rather than to the ether. The patients were given oxygen immediately after the operation and anticoagulants on the second day. Venous thrombosis of the legs developed in eight patients, occurring generally between the 3rd and 10th day. It was located in the right leg of four patients, the left leg of three, and both legs of one patient. However, the edema which followed disappeared rapidly and entirely. Bronchopneumonia developed in one patient on the eighth day but it was cured with antibiotics. There was no case of embolism. Results were gratifying in eight patients who have been well for several months; some of them have already returned to their jobs. A mild cardiocirculatory insufficiency is still present in two patients who, however, can walk if they follow a proper diet and proper medication. Four patients improved slightly, but the disease regressed rapidly to the preoperative stage. Two of them have since died. The operation was tolerated well and gave better results in patients with elevated pressures in the right ventricle (even double the normal values) but with normal or slightly increased atrial pressures. It was tolerated less well by patients with elevated atrial pressures. The good results brought about by this operation should not be entirely ascribed to the improved cardiovascular dynamics. A general change in tonus and contractility especially of the arterioles is suggested.

Congenital Absence of Tear Secretion.—Sjögren reports 14 cases of congenital absence of tear secretion which he found recorded in the literature, beginning with the first case described by Morton in 1844 and ending with a case observed by himself and Eriksen in 1950. The condition is usually of neurogenic origin, that is, it is due to aplasia of the secretory nuclei, or to the fact that the connection between the secretory center and the nerve tracts is lacking now and then in newborn infants. It may be caused by a congenital disturbance in the autonomic nervous system. It is possible that in a few cases aplasia of the lacrimal glands exists. This has not been definitely proved, but if such cases do occur they may perhaps be incomplete forms of congenital ectodermal dysplasia. Thus there seems to be a congenital form of keratoconjunctivitis sicca which differs fundamentally from the form which occurs adults; in infants there is aplasia, in adults, atrophy.

in the size of the ulcer. The patient may be discharged only when the lesion has disappeared completely and normal pliability to the gastric wall in the affected area has been restored. Then a regular radiologic examination of the stomach should be taken twice a year for the first three years and annually thereafter, even if digestive symptoms are no longer present.

Posthepatitic Cirrhosis.—Forty-three cases of cirrhosis were studied in which the clinical data strongly suggested that hepatitis of viral origin had been present. In all but two of these cases, jaundice had been present at some time during the course of the disease. No case was included in which there had been a history of exposure to hepatoxic chemicals, cardiac failure, thyrotoxicosis, hemolytic anemia, alcoholism, operation on the biliary ducts, or other complicating diseases. Necropsy excluded cases in which extrahepatic obstructive jaundice was present. The principal causes of death were hepatic insufficiency (81.4%) and hemorrhage (18.6%). The livers were classified grossly as lobar, nodular, and granular. The lobar and nodular livers were typical of so-called toxic or postnecrotic cirrhosis. The granular livers resembled Laennec's or alcoholic cirrhosis in many clinical and pathologic aspects; in seven of these granular livers the histopathologic appearance was identical with that observed in Laennec's cirrhosis. It is suggested that viral hepatitis may occasionally result in the morphologic equivalent of Laennec's or alcoholic cirrhosis. Aside from the granular group, however, the cases of posthepatitic cirrhosis revealed many differences from Laennec's cirrhosis. Among these were a younger age distribution, predominance of females, lesser incidence of ascites and greater incidence of jaundice as early symptoms, leukopenia and the relentless and rapid course. Anatomically, posthepatitic cirrhosis differs from most cases of Laennec's cirrhosis in that esophageal varices are less common, the livers are smaller, the regenerative nodules are larger and farther apart and large zones of atrophy are present. Histologically bizarre cellular forms are common and infiltration with fat is absent or slight in posthepatitic cirrhosis.

Calibration of Therapeutic X-Ray Generators. T. J. Wang.—p. 885.

Failures and False Localizations in Tracer Technique.—Corrigan and Hayden show that, although the tracer technique is a precise diagnostic procedure, failures and false localizations may occur. In recounting some of these false interpretations they mention a patient with a mass in the left side of the neck. The tracer study showed a distorted thyroid with some retrosternal extension and a poor concentration and very poor retention of the tracer in the mass. In reviewing the counts and the entire tracer pattern now the authors realize that it was a perfect pattern of thyroiditis, but at the time they believed it to be carcinoma of the thyroid. In another case blockage of the kidney had collected a portion of the tracer material and had led to the erroneous interpretation of a functioning metastasis from a carcinoma of the thyroid. After discussing a number of other failures, the authors say that as in the case of roentgen rays the limitations as well as the potentialities of the tracer technique must be understood. This physical technique will never supplant sound clinical judgment or expert radiological study. When used carefully in cooperation with the other specialties, its capabilities are almost unlimited. In 2,711 tracer studies conducted on 2,367 patients, the authors experienced a total of only 13 failures and false localizations. The most serious of these were three carcinomas of the thyroid which were missed and three cases which were believed to be carcinoma of the thyroid that later could not be proved. Four were cases of mediastinal involvement; only one of these was an utterly erroneous conclusion, and the other three were cases of correct identification of one of two entities present. In contrast, a total of 119 cases of carcinoma of the thyroid were identified correctly by tracer technique, 14 of which were totally unsuspected at the time tracer study was performed.

muscles so that the face, neck, and trunk appear obese and the extremities thin, muscular weakness, hypertension, osteoporosis, amenorrhea or impotence, hirsutism and acne in the absence of other evidences of virilization, thin skin with purplish striations and a tendency to ecchymosis, and a cervicothoracic fat pad. Usually the urine is alkaline, lymphopenia and eosinopenia are present, and carbohydrate tolerance is impaired. Some patients with Cushing's syndrome exhibit, as one manifestation of adrenal cortical hyperfunction, a disturbance of the plasma electrolytes which, in its classical form, is characterized by decreased concentrations of potassium and chloride, increased concentration of bicarbonate and increased pH. The concentration of sodium may or may not be increased. This condition has usually been designated as hypochloremic, hypopotassemic alkalosis. On the basis of observations at the Mayo Clinic, Sprague and Power summarize the electrolyte disturbances of Cushing's syndrome, which are a consequence of the action of excessive amounts of adrenal hormones, probably cortisone-like, as follows: Presumably in all cases there is a depletion of intracellular potassium and probably an increase in intracellular sodium. In some, particularly those in which the disease is severe, there is, in addition, a lowering of the extracellular concentration of potassium as measured in the blood plasma or serum. When hypopotassemia exists, and occasionally when it does not, there is likely to be hypochloremia and alkalosis. Hypernatremia, due to the Na-retaining activity of adrenal steroids, may or may not be present. Occasionally retention of sodium is sufficiently marked to cause edema. The muscular weakness that is characteristic of Cushing's syndrome is probably not solely a result of potassium deficiency, but rather in part a consequence of wasting of muscle due to the catabolic action of cortisone-like steroids on protein. However, extreme degrees of weakness, or even paralysis, are occasionally dramatically improved by administration of potassium. In such instances potassium deficiency appears to be an important factor in the muscular weakness. While administration of potassium chloride will correct the electrolyte abnormalities of Cushing's syndrome, it will not correct the other features of the syndrome.

Nonsyphilitic Interstitial Keratitis with Deafness.—Nonsyphilitic interstitial keratitis with deafness is rare, only 15 cases having been reported so far. It appears suddenly in young adults. The initial symptoms may involve one or both eyes, with redness, blurring of vision, pain, lacrimation, blepharospasm and subconjunctival hemorrhage; or the disturbances may involve the ear with symptoms similar to those of Ménière's syndrome, namely, nausea, vomiting, tinnitus, vertigo, and rapid development of deafness. The symptoms of the two systems may occur either within a few hours of each other or several months apart, but most commonly they follow within one or two weeks. A granular corneal infiltrate, patchy in distribution, is present mainly in the posterior half of the cornea, but the cornea is not thickened, and the retina is not involved. When vascularization and keratitic precipitates are present the visual acuity is diminished. Unilateral or bilateral inner-ear deafness with diminished or no vestibular responses develops. Neurological examination and reaction for syphilis are negative, and the cerebral fluid is normal. The course of the disease is chronic with one acute episode and daily varying symptoms in the same or from one to the other eye, or with several episodes and remissions in between. The prognosis is unfavorable since treatment is of little benefit although with cortisone the ocular sequelae may be minimized. The etiology of this syndrome is still unknown and has been ascribed to postvaccinial encephalitis and viral infection. On the basis of some cases in which a more generalized involvement was reported, the hypothesis was advanced that the generalized illness may have been polyangitis (periarteritis nodosa). This had varied from minimal perivascular lymphocytic infiltration to necrotic inflammation of all the vessels and granuloma formation with giant cells. The ocular and aural symptoms may have been only localized manifestations of the disease and the patients in whom the generalized disease was not reported may not have been followed until the generalized symptoms developed. The authors report the case of a 23-year-old woman in whom the vascular reactions occurred after two acute episodes of ocular and aural symptoms. Later the gastrointestinal tract, skin, heart, pleura, and sclera became involved, and there was a flare-up of the keratitis, abscess formation with periarteritis changes and appearance of giant cells with granuloma formation. The prognosis was favorable because there was never a major renal involvement. But although cortisone improved her condition, bilateral deafness, loss of vestibular function, and white corneal opacities have remained.

Late Results of Conservative Treatment of Gastric Ulcer.—A follow-up was made of 48 patients with gastric ulcer who were treated conservatively from 1931 to 1946. Results indicated that the prognosis of gastric ulcer under medical treatment is far from reassuring in view of the probability of present or future carcinoma and the incidence of recurrences and complications. There were 34 males and 14 females in this group; the youngest patient was 7 years old and four patients were more than 70 years old. A typical ulcer sequence pain was present in 34 patients, and massive bleeding in 17. Anemia was present in six and in five of them it was ascribed to gross bleeding. The symptoms before hospitalization had lasted two years in 16 patients, two to five years in 14, and more than five years in 16; the duration of the symptoms was not recorded in 2 patients. The ulcers were located in the lower third of the stomach in 13 patients, in the middle third in 17, and in the upper third in 17. One patient had multiple ulcers and seven had an associated duodenal ulcer. The symptoms had disappeared quickly within the first week of treatment in all the patients, and the associated diseases (mostly cardiovascular and pulmonary disorders) did not affect the clinical course of the ulcer. Three-fifths of the patients received optimal management whereas the others were discharged prematurely. Four patients were followed for more than 15 years, seven for 10 to 15 years, 20 for 5 to 10 years, and the others for about 2½ years. Only 11 patients have always remained free of ulcer symptoms, 7 are still well despite one or more recurrences of ulcer activity, and 2 patients have died of other causes. Of 20 patients who continued to have periodic exacerbations of the symptoms 6 have been operated on and 4 have been similarly advised. Eight patients have died of verified carcinoma of the stomach. When a diagnosis of gastric ulcer is made, the patient should be hospitalized immediately for evaluation and decision as to the best method of treatment. Conservative treatment is justified if after a trial period of approximately eight weeks serial roentgenograms reveal a progressive decrease in the size of the ulcer. The patient may be discharged only when the lesion has disappeared completely and normal pliability to the gastric wall in the affected area has been restored. Then a regular radiologic examination of the stomach should be taken twice a year for the first three years and annually thereafter, even if digestive symptoms are no longer present.

Posthepatitic Cirrhosis.—Forty-three cases of cirrhosis were studied in which the clinical data strongly suggested that hepatitis of viral origin had been present. In all but two of these cases, jaundice had been present at some time during the course of the disease. No case was included in which there had been a history of exposure to hepatoxic chemicals, cardiac failure, thyrotoxicosis, hemolytic anemia, alcoholism, operation on the biliary ducts, or other complicating diseases. Necropsy excluded cases in which extrahepatic obstructive jaundice was present. The principal causes of death were hepatic insufficiency (81.4%) and hemorrhage (18.6%). The livers were classified grossly as lobar, nodular, and granular. The lobar and nodular livers were typical of so-called toxic or postnecrotic cirrhosis. The granular livers resembled Laennec's or alcoholic cirrhosis in many clinical and pathologic aspects; in seven of these granular livers the histopathologic appearance was identical with that observed in Laennec's cirrhosis. It is suggested that viral hepatitis may occasionally result in the morphologic equivalent of Laennec's or alcoholic cirrhosis. Aside from the granular group, however, the cases of posthepatitic cirrhosis revealed many differences from Laennec's cirrhosis. Among these were a younger age distribution, predominance of females, lesser incidence of ascites and greater incidence of jaundice as early symptoms, leukopenia and the relentless and rapid course. Anatomically, posthepatitic cirrhosis differs from most cases of Laennec's cirrhosis in that esophageal varices are less common, the livers are smaller, the regenerative nodules are larger and farther apart and large zones of atrophy are present. Histologically bizarre cellular forms are common and infiltration with fat is absent or slight in posthepatitic cirrhosis.

Failures and False Localizations in Tracer Technique.—Corrigan and Hayden show that, although the tracer technique is a precise diagnostic procedure, failures and false localizations may occur. In recounting some of these false interpretations they mention a patient with a mass in the left side of the neck. The tracer study showed a distorted thyroid with some retrosternal extension and a poor concentration and very poor retention of the tracer in the mass. In reviewing the counts and the entire tracer pattern now the authors realize that it was a perfect pattern of thyroiditis, but at the time they believed it to be carcinoma of the thyroid. In another case blockage of the kidney had collected a portion of the tracer material and had led to the erroneous interpretation of a functioning metastasis from a carcinoma of the thyroid. After discussing a number of other failures, the authors say that as in the case of roentgen rays the limitations as well as the potentialities of the tracer technique must be understood. This physical technique will never supplant sound clinical judgment or expert radiological study. When used carefully in cooperation with the other specialties, its capabilities are almost unlimited. In 2,711 tracer studies conducted on 2,367 patients, the authors experienced a total of only 13 failures and false localizations. The most serious of these were three carcinomas of the thyroid which were missed and three cases which were believed to be carcinoma of the thyroid that later could not be proved. Four were cases of mediastinal involvement; only one of these was an utterly erroneous conclusion, and the other three were cases of correct identification of one of two entities present. In contrast, a total of 119 cases of carcinoma of the thyroid were identified correctly by tracer technique, 14 of which were totally unsuspected at the time tracer study was performed.

*Supply of Oxygen to Prematures and Appearance of Retrolental Fibroplasia. A. Huggert.—p. 147.

Administration of Oxygen and Retrolental Fibroplasia.—Huggert, in a previous paper, reported observations on the eyegrounds of 66 prematurely born infants with a birth weight of less than 2,600 gm. In many of these the fundus showed peripheral edema and changes in the caliber of the vessels, and more than 25% exhibited the picture similar to that regarded as the early stage of retrolental fibroplasia. Huggert reports further observations on 130 cases. The retinal vessels were often very narrow during the administration of oxygen, and vascular dilatation and peripheral edema occurred in most cases when oxygen was stopped, but in some instances even during the administration of oxygen. In the infants who had not been given oxygen, dilatation of the vessels and edema occurred immediately after birth. Retrolental fibroplasia developed in two of those who were treated with oxygen. Recently one of the infants in Huggert's clinic showed such severe retinal changes of early retrolental fibroplasia type that the infant was replaced in an incubator and was treated with oxygen. Under the oxygen treatment (with approximately 60% oxygen) there was a reversion of the retinal changes such as was reported by Szewczyk. Later, when the oxygen was gradually reduced, there was a reappearance of the vascular dilatation in one of the eyes which lasted for about a week and then disappeared. This case has been observed too recently for final evaluation. As further proof of a connection between oxygen therapy and retrolental fibroplasia the author points out that the latter was rarely if ever observed before 1941, when it was noted in an increasing number of prematurely born infants in the United States. In Sweden it began to be observed more frequently in 1944 and 1945. Incubators with special oxygen administration began to be generally used in the United States about 1940 and in Sweden in 1944. The incubators used in Sweden usually supply 45% oxygen, whereas many of the models used in the United States supply between 60 and 80% oxygen. If the oxygen content as such, or the rapid change-over from a high oxygen content to a normal one, is the decisive factor in retrolental fibroplasia, the stress involved in the change will be severer in the American type incubators with their more concentrated oxygen supply.

Radiologic Study of Pulmonary Artery (Contribution to Body Section Roentgenography): I. In Normal State and in Congenital Dilatations. G. Luzzatti and F. Rovelli.—p. 161.

Ligation of Inferior Vena Cava in Patients with Cardiovascular Diseases.—The inferior vena cava was ligated below its point of junction with the renal veins in 12 patients with cardiac decompensation caused by lesions of the mitral valve and in 3 patients with sclerosis of the pulmonary artery and hypercyanotic angina. The intracavitary pressure in the superior vena cava, the right atrium and right ventricle, and sometimes the inferior vena cava and the coronary sinus were recorded by catheterization of the right heart. Arterial and venous pressures, circulation time, and electrocardiograms were recorded before and after the operation, and capillaroscopy of the hands and feet was also made. Particular attention was given to the anesthesia and the position of the patient during the operation. Patients who for a long time have lain only in an orthopneic position should not be made to lie horizontally on the operative table. These patients were placed at a 35 to 45 degree angle and the plane of the table was slightly rotated to the left. A dose of 0.05 gm. of Etamyl (5,5-isoamylethylbarbiturate) or pentobarbital (Nembutal) was given to the patients three hours before the operation and again one hour later, then 1 cg. of morphine with 0.5 mg. of atropine was given one hour before the operation. Anesthesia was accomplished with thiopental (Pentothal) sodium, curare, procaine and ether. Only one patient died during the operation, but she had been placed in a position which was more horizontal than her usual position and death was ascribed to this fact rather than to the ether. The patients were given oxygen immediately after the operation and anticoagulants on the second day. Venous thrombosis of the legs developed in eight patients, occurring generally between the 3rd and 10th day. It was located in the right leg of four patients, the left leg of three, and both legs of one patient. However, the edema which followed disappeared rapidly and entirely. Bronchopneumonia developed in one patient on the eighth day but it was cured with antibiotics. There was no case of embolism. Results were gratifying in eight patients who have been well for several months; some of them have already returned to their jobs. A mild cardiocirculatory insufficiency is still present in two patients who, however, can walk if they follow a proper diet and proper medication. Four patients improved slightly, but the disease regressed rapidly to the preoperative stage. Two of them have since died. The operation was tolerated well and gave better results in patients with elevated pressures in the right ventricle (even double the normal values) but with normal or slightly increased atrial pressures. It was tolerated less well by patients with elevated atrial pressures. The good results brought about by this operation should not be entirely ascribed to the improved cardiovascular dynamics. A general change in tonus and contractility especially of the arterioles is suggested.

Congenital Absence of Tear Secretion.—Sjögren reports 14 cases of congenital absence of tear secretion which he found recorded in the literature, beginning with the first case described by Morton in 1844 and ending with a case observed by himself and Eriksen in 1950. The condition is usually of neurogenic origin, that is, it is due to aplasia of the secretory nuclei, or to the fact that the connection between the secretory center and the nerve tracts is lacking now and then in newborn infants. It may be caused by a congenital disturbance in the autonomic nervous system. It is possible that in a few cases aplasia of the lacrimal glands exists. This has not been definitely proved, but if such cases do occur they may perhaps be incomplete forms of congenital ectodermal dysplasia. Thus there seems to be a congenital form of keratoconjunctivitis sicca which differs fundamentally from the form which occurs in adults; in infants there is aplasia, in adults, atrophy.

*Surgical Treatment of Elephantiasis Nostras. P. Gagliardi.—p. 283.

Surgical Treatment of Elephantiasis Nostras.—The results of surgical treatment of elephantiasis nostras (chronic streptococcic lymphedema) are far from encouraging. Treatment of this disease should always be individualized, since the results depend on the degree of edema and lymph stasis. Rest, hot baths, massage, elastic bandages, and electrotherapy may prove beneficial when pachydermia has not yet developed. When the disease is complicated by sclerosis, treatment should consist of (1) intensive therapy with antibiotics and sulfonamides against the micro-organisms responsible for the infection in the lymphatics; (2) creation of new channels to eliminate or diminish the lymph stasis; and (3) removal of as much of the sclerotic tissue as possible. The sclerosis will impair the function of the lymphatics that have been spared by the disease and will affect the new pathways that were formed surgically. Handley's operation has given some good results in the treatment of this disease, but Kondoleon's operation has proved superior. It consists in removing large strips of the scarred and thickened aponeurosis so that the skin comes in contact with the deep tissues; connections are established between the superficial and the deep lymphatics and thus the lymph can drain through the lymphatics of the muscular tissue. Although recurrence is unavoidable, the operation is not futile since it brings relief and can be repeated without danger. The author reports his surgical results in two patients with elephantiasis nostras in the legs. The first was a 19-year-old man who had had the disease for two years. Kondoleon's operation was performed on both legs twice in three months. Each time penicillin and sulfonamides were given preoperatively. The patient's condition was improved. A follow-up five years after the last operation revealed that edema was no longer present in the thighs and feet, although it had increased slightly in the legs. He had long since resumed his work as a shepherd and was able to walk and stand for many hours of the day. The second patient was a 20-year-old woman in whom the disease, which involved the right leg only, had appeared at the time of her first menstruation. She was given penicillin and sulfonamides for three days and then Lanz's operation was performed. The size of the leg was diminished, but seven months later edema began to reappear. Kondoleon's operation was then performed and good results were obtained. The patient was well 10 months later and the edema was not present. At the time of writing, more than two years after the operation, the improvement was still present.

*Parinaud's Conjunctivitis and Cat Scratch Disease. A. W. C. van Veelen and P. D. Stibbe.—p. 1203.

Parinaud's Conjunctivitis and Cat Scratch Disease.—In 1948 van Veelen and Stibbe observed a 14-year-old girl, who had conjunctivitis, edema of the eyelids, swellings of the left ear and jaw, and enlargement of the regional lymph nodes. The disorder was diagnosed as Parinaud's conjunctivitis, but the etiology remained obscure. The conjunctival secretion was examined for molds, spirochetes, the Corynebacterium diphtheriae and several other organisms, but the results were always negative. Pus from the suppurating lymph nodes was likewise examined for various pathogenic organisms, but here again the tests remained negative, as did also the agglutination reactions for brucellosis, tularemia, typhoid, paratyphoid and typhus, serologic tests for syphilis, the complement fixation test for psittacosis and the search for the virus of venereal lymphogranuloma. In 1952, the girl was subjected to an intracutaneous test with the antigen of cat scratch disease. Since this test resulted in a positive reaction, it was assumed that the attack of conjunctivitis in 1948 was probably caused by the virus of cat scratch disease.

Progressive Scleroatrophy of the Thyroid Gland. H. P. Klotz, C. Sors and J. Avril.—p. 1740.

Obesity and Overeating.—The theory that obesity is merely the result of overeating presupposes that the obese person has normal physiological responses. Overeating is undoubtedly common among the obese, but overeating alone does not cause obesity. The metabolic processes and the changes produced in them by various factors enter into the problem of obesity. The metabolic defect which results in obesity is usually hereditary; it may be sufficient to produce obesity without overeating, or it may become operative only under special conditions, which may be neuropsychic in origin. The weight of a normal person is generally stable; overeating or excessive inactivity may result in weight gains, but when these factors are removed, the weight soon returns to its former level. Moderate dieting will correct physiological overweight of this kind, but in obesity there is a pronounced difference between the ease with which weight is gained and the extreme difficulty with which it is lost. Long continued overeating may transform a normal person into an obese one, and vice versa. The metabolic defect responsible for obesity affects several factors, chiefly tissular and neuropsychic. The disturbance in the adipose tissue, or lipophilia, characteristic of obesity is the result of changes in the cerebral cortex, which controls all the metabolic processes and is the predominant factor in producing appetite, and even hunger. The complex problem of obesity should therefore be reviewed in the light of the adaptive powers of the living body and the activity of the higher nervous system.

*Out-Patient Treatment of Malaria with Single Dose Intramuscular Chloroquine in Hyperendemic Area in West Africa. D. B. Jelliffe.—p. 235.

Treatment of Malaria with Single Intravenous Injection of Chloroquine.—According to Jelliffe chloroquine diphosphate has only recently come into fairly general use in malaria therapy in many parts of Africa, although a considerable amount of work has been undertaken on the effects of chloroquine in other parts of the world. Forty African children aged from 4 to 27 months, all of whom were clinically sick with malaria (Plasmodium falciparum 30, P. malariae eight, and mixed two) were treated as outpatients with a single intramuscular injection of chloroquine. Parasite clearance and clinical cure followed within two days although in some cases follow-up showed a reappearance of parasitemia after from two to six weeks, due either to reinfection or relapse. The author concludes that chloroquine, given as a single intramuscular injection (5 mg. of base per kilogram of body weight), is a rapidly effective treatment for malaria. No general or local toxic effects were observed. The absence of fibrotic gluteal nodules, sterile abscesses and small areas of chemical muscle necrosis, as seen not rarely in these malnourished, anemic infants following intramuscular administration of quinine, was particularly striking and encouraging.

BOOK REVIEWS

The Basis of Clinical Neurology: The Anatomy and Physiology of the Nervous System in Their Application to Clinical Neurology. By Samuel Brock, M.D., *Professor* of Neurology, College of Medicine, New York University, New York. Third edition. Cloth. $7. Pp. 510, with 124 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

Since 1937 this book has served a most useful purpose in correlating clinical neurology with the basic anatomy and physiology of the nervous system. This edition is brought up-to-date and thus continues to fulfill a real need. A few limited sections have been prepared by other authors, notably, those on electroencephalography and electromyography by Dr. Paul F. A. Hoefer, on electrodiagnostic methods by Dr. Joseph Moldaver, on visual pathways by Dr. Max Chamlin, on cerebral angiography by Drs. Leo M. Davidfoff and Emanuel Feiring, and on sensory extinction by Dr. Morris Bender. The entire book seems to have received the author's careful attention in this revision. There is little to criticize in the book; however, at least two of the illustrations (fig. 68 and 115) are poorly reproduced and should be replaced. The index, although useful, is incomplete. In a cursory examination of it several things were missed, among them the principal arteries of the brain.

Sympathetic Control of Human Blood Vessels. By H. Barcroft, M.A., M.D., M.R.C.P., Professor of Physiology, St. Thomas's Hospital Medical School, London, and H. J. C. Swan, Ph.D., M.B., B.S., Research Associate, Mayo Clinic, Rochester, Minnesota, Number 1, monographs of Physiological Society. Editors: L. E. Bayliss, W. Feldberg, A. L. Hodgkin. Cloth. $3.75. Pp. 165, with illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; Edward Arnold & Co., 41-43 Maddox St., London, W.1, 1953.

This interesting book is published as a monograph of the Physiological Society. It presents in condensed form the role of the sympathetic nerves in the control of the blood vessels, particularly those of the muscle and the skin of the extremities. The physiological principles governing use of sympathectomy, norepinephrine and epinephrine, and the adrenergic blocking drugs are well presented, with appropriate illustrations. One chapter is devoted to the pheochromocytomas and another to the vasovagal syndrome. The senior author is an authority with world-wide recognition. The monograph makes available fundamental concepts, principles, and knowledge based upon contributions by authorities in several countries, and it is highly recommended as informative and concise reading for all physicians, medical students, and physiologists. It develops principles directly concerned with the clinical aspects of peripheral vascular disease and methods of study but does not cover differential diagnosis and treatment. The reader is thus given the basis upon which diagnosis and treatment are possible.

An Introduction to Public Health. By Harry S. Mustard, M.D., LL.D., Executive Director, State Charities Aid Association (N. Y.), New York. Third edition. Cloth. $4.25. Pp. 315. The Macmillan Company, 60 Fifth Avenue, New York 11, 1953.

This edition appears 9 years after the second edition and 18 years after the first edition. What originally started to be a textbook for the professional worker in public health has now been redesigned as a textbook and a reference for persons interested in problems of public health but who may not be professionally involved in public health administration. New chapters have been added on mental health and health education, and many of the chapters have been rewritten with the addition of new material and the deletion of old or outdated material.

In attempting to span a broad range of interest, Dr. Mustard has produced a book that is not sufficiently technical to be of interest to the professional public health worker but at the same time contains too much detail to give a clear overview of public health administration to the nonprofessional college student or the citizen who wishes to have some understanding of the public health operations in his community. Much of the quoted data are already out of date, and though the book may give an impression of the magnitude of certain activities it could not be used safely as a current reference. In general, the concepts expressed are standard points of view in the middle course of public health thinking. The descriptions of the various functions in a public health program give a reasonably accurate picture of the average program. "An Introduction to Public Health" should be of interest to most physicians in private practice and to those who are associated with any of the many phases of public health administration. If all physicians would read this volume, the health officer would have a much easier job in developing cooperative relationships with the practitioners of his community.

Lectures on the Scientific Basis of Medicine. Volume I: 1951-52. British Postgraduate Medical Federation, University of London. Cloth. 30s. Pp. 396, with illustrations. University of London, Athlone Press, London [distributed by Constable & Co., Ltd., 10-12 Orange St., Leicester Sq., London, W.C.2], 1953.

This book has been designed to appeal widely not only to busy physicians who have little time to read exhaustively but especially to young research workers, to teachers in the preclinical and clinical sciences, and to clinicians who will become consultants. The subjects included illustrate the methods by which new and fundamental knowledge has been acquired; some of the topics contain fresh observations; and others consist chiefly of matter that has been recently published elsewhere, and still others review recent progress in a particular field against a background of earlier advances. Beginning with a discussion of the scientific approach to medical research, the text covers a series of highly informative, although dissimilar, subjects; for example, lability of blood pressure, effects of hemorrhage on the cardiovascular system in man, tissue response to injury, the physiological basis of visual sensation, antibacterial immunity, antibodies, normal and pathological physiology of the kidney, aging, growth of the human at the time of adolescence, and biological action of radiation. This book should prove very helpful.

Pathology in Surgery. By Edwin F. Hirsch, Ph.D., M.D., Director of Henry Baird Favill Laboratory and Pathologist of St. Luke's Hospital, Chicago. Cloth. $10. Pp. 474, with 390 illustrations (photography by Inez M. Porter). Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

Dr. Hirsch states: "Readers should remember that this text is not one in either general or special pathology, although both are fundamental." The volume was written not only for pathologists but for surgeons and surgical residents, even surgical residents in the various specialties. It may also be valuable to medical students who have had some training in general pathology. One is amazed at how much material the author has been able to include in this small monograph. The material from 11 separate fields includes: the respiratory system, the digestive system, the urinary system, the female reproductive system, the male reproductive system, the nervous system, the liver, gallbladder, and spleen, the ductus glands, and the skin. The index and the illustrations are excellent. The presentations are brief and concise, but adequate, and the amount of material included in the discussion is excellent.

For anyone who wishes a ready reference work in surgical pathology, this volume will prove useful. It will be useful to residents, for whom it was primarily prepared, and to men who are attempting to prepare for board examinations. Because of its excellent illustrations, it will give the reader a clearer concept of the lesion in which he has an interest.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specificially so stated.

QUERIES AND MINOR NOTES

SCHOOL CRAYONS AND PAINTS

To the Editor:—*What paints and crayons are safe for elementary school children to use in their school work and at home? Is turpentine a safe paint thinner and brush cleaner? How dangerous is it if splashed in the eyes?*

L. C. N. Wayland, M.D., Santa Barbara, Calif.

Answer.—Obviously school art crayons and paints should not contain lead, cadmium, benzol, methyl alcohol, carbon tetrachloride, or kindred agents. To some extent, the natural coloring agents are less harmful than the synthetic, but there are exceptions. Wax crayons colored with aniline dyes somewhat frequently cause methemoglobinemia, but this is chiefly due to chewing of the waxes rather than to proper school use. The paranitraniline colors are notable offenders. One difficulty springs from the fact that many art materials are sensitizers and on a somewhat unpredictable basis. Even the sizing materials and fixatives common to art work sometimes serve as sensitizing agents. The pigment in some colored pencils, such as the methyl violet in indelible pencils, may serve as a direct damaging agent to the eyes, that is, particles of methyl violet from indelible pencils entering the eye are peculiarly damaging to the cornea. Freedom from exposure in the art classroom is more a matter of supervision than of materials. Turpentine as mentioned serves as a good example. Ordinary turpentine is a toxic agent, a skin irritant, a sensitizer, and readily flammable. Intelligent supervision may eliminate all these threats. Both turpentine and rubbing alcohol, which chiefly is isopropyl alcohol, are eye irritants, the former being the greater offender. Brushes, if stored in a wet medium, should be kept in raw linseed oil. Safety in the art room is best provided through instructor supervision; however, certain producers of art supplies for elementary school use seek to avoid materials that may injure health.

POLYPOID TUMOR OF STOMACH

To the Editor:—*Could polypoid tumors of the cardiac end of the stomach rupture during the lifting of an object weighing 200 lb. (90.7 kg.) and could such a rupture result in slow bleeding, anemia, and death two months later?*

M.D., Massachusetts.

Answer.—It is possible that heavy lifting could result in rupture of a polypoid tumor in the cardiac portion of the stomach and cause progressive bleeding and anemia with subsequent death. It would, however, be difficult to prove that this has occurred, since it is doubtful that the muscular contractions incident to heavy lifting would produce more trauma to a tumor in the cavity of the stomach than would be produced daily by the ingestion of food and drink and by gastric peristalsis. A direct blow to the abdomen would be much more likely to produce such rupture or disorganization of a friable tumor mass.

CONGENITAL NYSTAGMUS

To the Editor:—*Are there any new drugs that are of help to patients with congenital nystagmus?*

Z. W. Gramling, M.D., Orangeburg, S. C.

Answer.—There is no treatment available for congenital nystagmus. Certain drugs, such as barbiturates given intravenously, may cause temporary cessation of nystagmus on direct forward gaze, but these same drugs also cause the development of nystagmus on lateral gaze. Congenital nystagmus, usually inherited, should be differentiated from so-called ocular nystagmus, which is the result of defective vision dating either from birth or from the occurrence of some ocular lesion before the development of fixation. Adequate correction of vision in the latter group may be of some benefit but will not control the nystagmus once it has developed.

FATALITIES ATTRIBUTED TO BOXING

To the Editor:—*I would appreciate information on the number of deaths attributed to boxing and on the pathological findings associated with these fatal injuries.*

Henry Fisketti, M.D., Duluth, Minn.

Answer.—Complete and accurate morbidity and fatality statistics of injuries and deaths attributable to boxing leave much to be desired. The answer to your questions on the number and causes of death in this sport is of necessity subject to inherent discrepancies, debatable interpretations, and errors of omission. In a relatively complete world survey of all fatalities in boxing, professional and amateur, including the military, from 1946 to 1952, however, it is estimated that about 2,200,000 bouts have taken place. Roughly 50% of the deaths in the ring during these same years occurred outside continental United States. The following table is an annual breakdown of these mortality statistics.

Year	Total Deaths	Professional	Amateur
1946	14	12	3
1947	10	5	5
1948	14	9	5
1949	19	12	7
1950	11	7	4
1951	12	3	9
1952	7*	3	4

* Deaths as of July, 1952.

For a more detailed analysis of this material, particularly the pathophysiological aspects of the causes of deaths reported above, the following references may be consulted: (1) Jokl, E.: The Medical Aspects of Boxing, South Africa, J. L. Van Schaik, Ltd., 1949; (2) Symposium on the Medical Aspects of Boxing, sponsored by the New York State Athletic Commission, New York, July 25-26, 1952, R. Christenberry, commissioner; (3) Christenberry, R. K.: Boxing in New York, Correspondence, *J.A.M.A.* **151**:317 (Jan. 24) 1953; and (4) Gonzales, T. A.: Fatal Injuries in Competitive Sports, *J.A.M.A.* **146**:1506 (Aug. 18) 1951.

BLACK DISCOLORATION BENEATH GOLD RING

To the Editor:—*After wearing a 14 carat gold ring for six months, a black discoloration of the skin under the ring and on the adjacent fingers developed in a patient. The salesperson told him that this was due to "acidity of his system." Is this a logical explanation?*

M.D., Washington.

Answer.—Fourteen carat gold ordinarily is alloyed with copper, although in white gold the chief alloy agent is nickel. Staining from white gold is not likely to occur. Both gold and copper are slightly soluble. Some persons secrete sweat containing traces of sulfur. A larger number of persons engage in work involving exposure to sulfur compounds that lend themselves to sulfide formation. The black discoloration probably is due to the presence of a metallic sulfide, formed as the result of action between the sulfur and metal from the ring. Such small amounts are involved that damage is not likely to be produced, and the main problem is a cosmetic one, although an allergy may be established. Certain jewelers' lacquers, when baked onto a gold object, may prevent this discoloration, not permanently but for a long time.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

TREATMENT OF MENOPAUSAL SYMPTOMS

To the Editor:—*A patient, 51 years of age, has severe menopausal symptoms, including hot flashes and nervousness. In her last menstrual period, which occurred five months ago, the flow was scanty. Nine years ago she had a radical mastectomy for carcinoma of the right breast. There is no evidence of recurrence. Is the use of estrogen therapy contraindicated? If not, are natural or synthetic estrogens more advantageous?*

W. P. Skirball, M.D., Sandusky, Ohio.

Answer.—Entirely apart from the history of carcinoma of the breast apparently cured by mastectomy nine years ago, and applying to all cases of menopausal vasomotor symptoms, the therapeutic employment of estrogens should be held to the minimum required for symptomatic relief; they should be used orally and not hypodermically and should be administered intermittently, only when and if symptoms are severe. Continuous estrogen therapy carries with it the hazard of inducing postmenopausal bleeding and of prolonging the menopause by retarding the inevitable pituitary-ovarian readjustment. There is no evidence that moderate and intermittent estrogen therapy would carry with it any hazard of inciting cancer recurrence in a patient like the one described. Some physicians claim that the natural hormones bring about a greater sense of well-being than do the synthetic hormones, but this consultant has not observed any noteworthy difference. Should one wish to avoid even a speculative hazard in such cases, testosterone may be used, since it relieves the vasomotor symptoms, although not as effectively as the estrogens.

BLURRED VISION

To the Editor:—*A young man complains that his eyes "blur" at times. I have been unable to find this symptom mentioned in any book on ophthalmology. Can you advise me as to the causes of this condition?*

William E. Stevens, M.D., San Francisco.

Answer.—Indistinct, blurred, or obscured distant vision in children and in adults may be caused by uncorrected hyperopia, uncorrected or increasing myopia, opacities of the lens, degeneration of the macula, nystagmus of infantile origin, or the toxic action of drugs or bacteria on the retina and optic nerve as well as by the toxic action of tobacco.

POST-HERPETIC NEURALGIA

To the Editor:—*What is the proper treatment for the chronic neuralgia that follows herpes zoster?*

Harry F. Watt, M.D., Ocala, Fla.

Answer.—There is no treatment that will with certainty relieve post-herpetic neuralgia. Posterior root section, chordotomy, and sympathectomy have been tried in a number of patients but have not produced relief. A few cases have been reported in which removal of the skin involved by herpetic lesions or complete circumscription and undercutting of the involved skin in stages has given relief. Such a procedure may be tried in a case sufficiently severe to warrant such drastic treatment, but it must be realized by both the surgeon and the patient that there is no certainty of a cure.

BRAIN INJURIES

To the Editor:—*I am curious about two conditions that accompany certain types of brain injuries. The first is a low diastolic blood pressure, sometimes 0 mm. Hg, that occurs in the presence of a normal systolic pressure. The other, which I have noted rarely, is the occurrence, during patella reflex examination of one leg, of a "jerk" in the other leg. What is the physiological basis for these findings?*

M.D., South Carolina.

Answer.—A lowered diastolic pressure is not commonly seen in persons who have had an intracranial cerebral injury and is not to be correlated with such an injury. It is not clear what is meant by the statement that the opposite leg "jerks" when elicitation of the patella reflex is attempted. To answer this question it would be necessary to know which muscles contracted to produce the jerk observed. In many instances in which the tendon reflexes are hyperactive, percussion of one patellar tendon will cause a contraction of the adductor muscles of the opposite thigh and cause that thigh to jerk medially. If this is the response to which the inquirer refers, the explanation is that the blow on the knee is transmitted upward by the femur to the pelvis, and this blow transmitted to the pelvis on one side causes stretching of the adductor muscles of the opposite thigh, which respond by contracting. All tendon reflexes are, in fact, stretch reflexes and are elicited whenever the affected muscles are stretched suddenly.

POLIOMYELITIS AND TONSILLECTOMY

To the Editor:—*A child who had poliomyelitis three and one-half years ago is now in need of a tonsillectomy. Would there be any danger of activating the virus in her throat by the operation, with the possible result of the occurrence of bulbar paralysis?*

Samuel Newman, M.D., Danville, Va.

Answer.—All available evidence indicates that infection by the virus of poliomyelitis is of limited duration. Horstmann, Ward, and Melnick (*J. Clin. Investigation* 25:278, 1946) studied the persistence of excretion of virus in the stools of 61 patients. In only one was virus found as late as 12 weeks after onset of the disease. Tests for virus in throat swabs have revealed its presence there for an even briefer period, and no instance has been recorded of the presence of virus for as long as three and a half years. There is, accordingly, no reason to believe that a tonsillectomy at this time may activate virus remaining from the earlier infection. The patient referred to is presumably immune to at least one of the three known types of poliomyelitis virus (the one responsible for his earlier attack). The danger of the occurrence of poliomyelitis following tonsillectomy should, therefore, be somewhat less than it would be if he were susceptible to all three types.

SINUSITIS IN CHILDREN

To the Editor:—*What is the accepted treatment for sinusitis in children between the ages of 2 and 10 years? Is antrostomy done routinely in children? What is the indication for it?*

Hans M. Schapire, M.D., Mattoon, Ill.

Answer.—Treatment for sinusitis in children between the ages of 2 and 10 years is essentially conservative. In the case of acute purulent sinusitis, treatment is both general and local. Bedrest, especially if fever is present, is valuable if the child's room is properly ventilated, with an approximate temperature of 70 F and a humidity of 40 to 50%. Systemic use of antibiotics or chemotherapeutic agents in appropriate dosage for children is exceedingly effective in the severer forms of acute sinusitis. As in the case of adults, medical treatment for sinusitis in children consists mainly in the general measures that favor restoration and maintenance of normal nasal and sinal physiological states. Ventilation of the nasal and sinal structures is effected by the rational use of 0.25 to 0.5% ephedrine sulfate in isotonic sodium chloride solution or any other suitable nasal vasoconstrictor that can relieve nasal congestion, improve nasal ventilation, and, when judiciously employed, aid in promoting adequate drainage from paranasal sinuses by opening obstructed ostia. Treatment for the chronic forms of sinusitis in young children includes such measures as irrigation, displacement therapy, and the elimination of possible allergic factors and obstructing hypertrophic adenoid tissue. Intranasal antrostomy should not be done routinely in children. Only in long-standing, resistant cases, and only in the event well-established measures have failed, should consideration be given to a more permanent form of drainage by means of intranasal antrostomy. A great deal depends on the ability of the physician to evaluate accurately the total problem, including the child's environment and background, and to apply therapy accordingly.

MILITARY MEDICINE

CHAIRMAN'S ADDRESS

Richard A. Kern, M.D., Philadelphia

A year ago, when the Section on Military Medicine held its first meeting as an established section of the Scientific Assembly of the American Medical Association, the most significant presentation on the program was the address of the chairman. At that time Dr. Melvin Casberg clearly defined the term military medicine, and outlined the functions and purposes that this section should serve. He also traced the evolution, in the office of the Secretary of Defense, of the Armed Forces Medical Policy Council. This was a most important development as far as the medical profession was concerned, since it provided for the first time at that high level an agency for the general direction, coordination, and control of the medical services of the three military departments and for a practical approach to the common problems of military and civilian medicine. All future chairmen of this section are indebted to Dr. Casberg for this fine chart of past accomplishment, current conditions, and future progress. The task of the present chairman is the easier, since his predecessor has piloted the ship from its very launching through the narrower reaches of the upper channel. Nevertheless, he must log briefly the course made good and the existing and foreseeable hazards, before turning over the wheel to his relief.

Military medicine is the application of sound medical principles to the prevention and management of injury and disease under the conditions imposed by war. These conditions bring into play factors of environment, of numbers of patients, and of administration that differ sharply from those of civilian medical practice. Military medicine further includes the development of new applications of basic medical principles to meet the changing conditions of modern warfare. The field of military medicine therefore involves a never-ending interchange of thought and practice between scientific medicine (with which all physicians are concerned) and the science of war (which concerns the military professions, medical as well as line and other staff corps). This section offers a useful channel through which such an interchange of information may take place in both directions. Medical scientists can here find a forum to present medical advances that have special significance for military uses. Military scientists can here discuss the solutions of new problems posed by changing techniques of warfare.

It would, however, be a narrow concept of the potential usefulness of this section to think of it only in terms of this annual session, with its papers and exhibits. The great majority of the members of this section are civilian physicians who are also medical reservists of the armed forces. As such, we have a double interest and function. We seek and find here the chance to learn new things in military medicine from our colleagues who have made military medicine their life's work; but we should also disseminate that new knowledge and interpret our field to our civilian colleagues, and this we must do all through the year and throughout the country. This does not mean that we should organize more sections on military medicine at state and county levels. That would defeat our purpose of spreading our information as widely as possible. On the contrary, both officers and members of this section should offer their services (not wait to be asked) to program committees of state and county medical societies and be willing to accept such assignments whenever possible. They might take the form of arranging a whole program on a given occasion, but in general they might better be single presentations as part of almost any kind of meeting, so as to reach as large a number of physicians as possible. This section could achieve its greatest usefulness by the sustained fostering of such a program.

Our civilian colleagues have important reasons for welcoming a steady flow of information about military medicine. In case of war, they would constitute the vast proportion of the medical officer personnel of the armed forces. Many physicians would therefore be helped by some foreknowledge of military medicine, even if at this moment they do not hold reserve commissions. But military medicine has a wider potential application, for the conditions of major disaster are quite similar to those of actual warfare. Practically all physicians, especially

Professor of Medicine, Temple University School of Medicine.

Read before the Section on Military Medicine at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

those who live in target areas of potential attack by an enemy, should therefore know the basic facts of military medicine and should be kept abreast of major developments.

This suggests a further need, namely, some instruction in the medical principles of civil defense and in military medicine in all our medical schools. This does not mean another department to be forced into an already crowded curriculum, nor does it mean a few lectures casually slipped in toward the end of the senior year. It does call for a sustained program of instruction throughout the four years, integrated with the existing framework of teaching of the usual medical subjects, and carried out by teachers fitted by background and continued training so to do. Above all, it calls for the fixing, by the dean, of the responsibility for such instruction in a suitable committee of the faculty. Therefore, the pilot programs that were begun this year in five medical schools under the aegis of the Committee on Medical Education for National Defense (MEND) should be watched with great interest. Preliminary reports are highly favorable.

PROCUREMENT OF MEDICAL PERSONNEL

Up to this point the discussion has dealt with military medicine, but it is impossible to separate that topic wholly from the subject of those who practice it, the medical officers. It is now 13 years since the bulk of medical service to the armed forces was provided by a permanent staff of military career physicians. Today, two-thirds of all medical officers on active duty are reservists. It may be a score of years or more before that proportion is reversed. The procurement of both types of medical officers is therefore a matter of the greatest personal interest and concern to all physicians.

We are interested in the building up of the several permanent medical corps to the point where they will constitute two-thirds of the number needed for the present expanded military establishment. This means doubling the present number on the rolls. The significance of this to civilian practice becomes clearer when it is remembered that every permanent medical officer would, over the next six years, replace four reservists.

We are interested in a program of inducting physicians from civilian ranks that would be fair to them, that would maintain an adequate medical service to the public, and that would not unduly dislocate an orderly scheme of postgraduate training. We are interested in the efficient utilization of medical personnel to the fullest extent and within the scope of professional qualifications that circumstances allow, and for only such purposes as justify the diversion of physicians from civilian to military practice. This involves the freest reciprocal use of facilities and personnel between the several services. It does not mean, in my opinion, a single medical corps for all services. In the armed forces a physician is also an officer of Army, Navy, or Air Force. It is no more logical to make a physician an officer of all three than it would be to make any other type of officer polyvalent. It is hard enough, in the time available, to make one kind of officer out of most civilian physicians.

The major problems relating to medical personnel present themselves in the Department of Defense, where until April 1, 1953, they were in the province of the Armed Forces Medical Policy Council. The replacement of that council and the reorganization of the agency dealing with matters of health and medicine in the purview of the Department of Defense will be discussed at this session by the man best qualified on every count to do so, the erstwhile chairman of the Armed Forces Medical Policy Council and now the assistant to the Secretary of Defense (health and medical), Dr. Melvin A. Casberg. The outbreak of war in Korea two years ago provoked the precipitate need for, and the adoption of, a program to provide physicians for the armed forces. This was the "doctor-draft" law (public law 779). The law expired on June 30, 1953, but the need for this law continues. Into its replacement has gone an unprecedented amount of cooperative study and planning by many representatives of the widest range of interested groups. It is hoped that the new law will, as Dr. Casberg expressed it, "step as lightly upon as few toes as possible."

The recruitment of an ample number of physicians who would make a career of military medicine presents an as yet wholly unsolved problem. The virtual stopping of all accessions to the permanent services since the onset of the Korean episode, as contrasted with a fairly constant inflow during many preceding years, strongly suggests that its major cause lies in the "freeze" in effect since 1951, which precludes the acceptance of resignations from the regular services except under conditions of extreme hardship. Young physicians, and even more so their wives, will not enter a service from which, should they not find it to their liking, there is no means of escape. It is therefore highly desirable that they be offered provisional first commissions on a three year basis. An additional inducement might well be offered by the scholarship plan, approved in principle by the Armed Forces Medical Policy Council and reported to this session a year ago by Dr. Casberg. It involves the subvention of acceptable students in medical schools, on nomination by their deans, with obligated military service year for year, and with an escape clause on the basis of monetary refund.

I wish to add to that of others my own disapproval of a device of recruitment that some have suggested; the creation by the government of one or more medical schools to provide physicians for the military and perhaps other federal services. Dr. Casberg last year stressed the obvious dangers: medical inbreeding, a narrowed outlook, an unwarranted self-satisfaction, a loss of contact between civilian and military medicine, and the formation of a medicomilitary caste. The strength of the armed forces medical profession today is rooted in the diversified educational resources of its members. On their diversified origins is also based the solidarity of the military medical profession with the civilian. Each physician of the regular services has a score or more of classmates in civilian practice who see in him not only a bond of professional fellowship with those services but a guarantee of the basic excellence and soundness of viewpoint of the military medical profession. All this would be jeopardized by a separate federal medical school system.

We are not a military-minded people. Many of us are frankly suspicious of military establishments as tools of aggression. As a result, we have found ourselves tragically unprepared at the outbreak of wars. In 1861, Lincoln dared call for only 90-day volunteers. In the same year in Georgia, Gov. Joe Brown raised militia to serve only within that sovereign state, a policy that he continued in succeeding years to the detriment of the Southern cause. Yet, in 1863, he was reelected by the handsomest of majorities. After each war we have demobilized with unseemly haste, leaving to a few career men the thankless task of looking to our defenses.

The settlers of colonial and frontier days had a more realistic viewpoint. In their experience, war was not heralded by formal declaration, and the cessation of hostilities meant only an armed truce. Therefore, the flintlock musket, loaded and primed, was always hung over the mantel to keep the powder dry. That custom was even safeguarded by the Constitution in the second article of the Bill of Rights. The whole world is in much the same state today. Our hope of national survival rests on being prepared to meet any attack. An adequate trained reserve is the keystone of that preparedness. The chief reason for the existence of this section is to assist in the continued training of our medical reserve. Let us all, therefore, rededicate ourselves to the fulfillment of that purpose.

3401 N. Broad St. (40).

CEREBRAL EDEMA AND ITS RELATION TO BARBITURIC ACID POISONING

Lloyd H. Mousel, M.D., Seattle

The clinical courses of patients who have undergone severe episodes of anoxia are similar. Severity of symptoms and pathological changes depend on the amount of oxygen supplied to the vital organs, the ability of the vital organs to utilize the available oxygen, and the susceptibility of the person to anoxic insults.

Courville[1] gave a complete and classic description of the clinical course and pathological findings in persons who had suffered acute oxygen lack. World War II stimulated interest and investigations in respiratory and circulatory physiology because of the need for high altitude flying. This more than any other factor stimulated a widespread interest in oxygen demand and supply. It changed the pattern of our thinking and emphasized the disastrous results of even mild anoxia. We began to understand that even slightly diminished oxygen tension could cause mental confusion and unconsciousness and also that severer lack of oxygen could result in death within a comparatively short time. We can now review our clinical experiences with a clearer concept of the results of tissue anoxia from any cause.

Lucas[2] reported on an experimental and clinical study of the results of anoxia on the central nervous system. He recorded the effects of mild and prolonged anoxia on the brains of animals and the effects of anoxia on the human brain. Rats survived only one-half to one hour in an atmosphere containing 3% or 4% oxygen. As the oxygen concentration was increased the survival time lengthened, until animals kept in an atmosphere of 9% oxygen survived approximately three days. Animals were then placed in an atmosphere of 9% oxygen for seven hours per day. This group survived for about 9 or 10 days. Microscopic examination of brain tissue taken from animals that died during the experiments showed very little, but, as the anoxia became more prolonged, evidence of damage appeared. This consisted of destruction of nerve cells and loss of Nissl staining properties. The most striking evidence of cell damage was loss of staining qualities of the large pyramidal cells and their eventual disappearance. Small round cells became more deeply stained, more irregular in outline, and shrunken in appearance. A great increase in the number of capillaries was observed throughout the brain. This report indicates that prolonged mild anoxia, in animals at least, can cause severe damage to the brain and that the effect is cumulative.

Seldon and associates[3] have postulated that cerebral edema might be responsible for postanesthetic encephalopathy and have suggested this as a basis for rational treatment. They gave the results of treatment of cerebral anoxia by administration of human serum albumin. Lucas[4] stated that the earliest change in the anoxic brain is an intracellular edema. If this is reabsorbed readily the cell recovers, but if it persists then by purely mechanical means oxygen will be denied rapid access to the cell, so that the anoxia becomes worse and a vicious circle is established that leads to cellular death. He states that withdrawal of fluid from the brain by osmotic means is the basic principle underlying treatment of cerebral edema. This can best be done by use of concentrated human serum in a dose not exceeding 50 ml. per hour, for too rapid dehydration may produce convulsions.

During the last decade the problem of managing patients with acute barbiturate poisoning has grown steadily. The stress of modern living in a highly competitive and uncertain world has led many to seek permanent escape from seemingly insurmountable problems. Barbiturates have claimed their share of these unfortunate victims. The number of deaths from barbiturate poisoning each year probably cannot be determined accurately. Isbell[5] estimates 1,500 deaths per year in the United States, an 8% mortality of all persons

---

Read before the Section on Anesthesiology at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

Human serum albumin used in this study was furnished by the American National Red Cross through Dr. Louis K. Diamond.

with barbiturate poisoning. Reed, Driggs, and Foote[6] reported on 209 persons treated between 1940 and 1949, with a mortality of 13.4%. They reported a later series of 91 cases with a mortality of 5.5%. These figures represent the results obtained from standard therapy in well-organized services. The mortality figures probably are higher on a national basis.

The treatment of barbiturate intoxication has become fairly standardized, one or a combination of the analeptic drugs being employed along with general supportive therapy. The drugs used most commonly are picrotoxin, amphetamine, caffeine, pentylenetetrazol (Metrazol), nikethamide (Coramine), with picrotoxin the most widely used. Mousel and Essex[7] found that the analeptics were not only useless but actually harmful in treatment of barbiturate overdose. Schmidt[8] wrote, "Direct studies of the oxygen consumption of the brain in situ have shown that cerebral metabolic activity runs parallel to cerebral functional activity and that convulsants may lead to cerebral anoxia (with all its consequences) because they increase oxygen demand beyond the available supply." Reed, Driggs, and Foote[6] reported several deaths among patients with cardiac arrhythmia who had received fairly large doses of picrotoxin, amphetamine, and caffeine, or a combination of these drugs.

Fisher, Walker, and Plummer[9] found that in dogs receiving pentobarbital by mouth the maximum blood concentration was reached within two hours of ingestion and remained constant for several hours. At 6 hours the blood concentration began to decrease, and at 12 hours the blood concentration had fallen to less than 50%. This pattern is probably similar with ingestion of any of the short-acting barbiturates. Why then do patients undergo prolonged periods of deep depression ending either in death or slow recovery? This condition must be ascribed to cerebral edema prolonging the anoxia instead of the original insult or prolonged action of the drug.

On the supposition that cerebral edema is probably responsible for the severe complications frequently seen in barbiturate poisoning, a therapeutic plan has been formulated for the treatment of these patients with 25% salt-poor human serum albumin. Three patients with severe barbiturate intoxication have been successfully treated since 1949. All were treated with analeptic drugs before the serum albumin was administered, and in each instance the analeptics failed to improve the patient's condition.

REPORT OF CASES

CASE 1.—A 25-year-old nurse was admitted to the hospital at 3:15 p. m. on April 3, 1949. She had last been seen in a conscious condition at 9:00 p. m. the previous day. At 11:00 a. m. on the day of admission she was found in a comatose condition. Pentylenetetrazol was administered in the home with no clinical response other than coughing. On admission her blood pressure was 100/50 mm. Hg, pulse rate 112 per minute, and the skin was pale and cool; the pupils were approximately 3 ml. in diameter, were uniform, and reacted to light. Physical examination showed no corneal, biceps, triceps, knee, ankle, or Babinski reflexes. Her body temperature was 97.8 F. The blood sugar level was 116 mg. per 100 cc. The therapy and clinical course are shown in table 1.

At 2:00 *p. m. on April 4, her respirations were very labored* and caused loud bubbling sounds. A large amount of thick, brown material was aspirated by bronchoscope. Her color appeared slightly improved, and the body temperature was 105.8 F by axilla. An intravenous injection of 100 cc. (25 gm.) of salt-poor human serum albumin was given. Alcohol rubs had no effect in lowering body temperature. The patient was then packed in chipped ice, one-half the body being covered at a time. Her temperature dropped promptly to 102.2 F, and the ice packs were removed. Four hours later the temperature went up to 103.8 F by axilla, and ice was once more applied. The temperature dropped sharply to 101.2 F. At noon on April 5, the patient was still comatose. Deep tendon reflexes were hyperactive, blood pressure was 124/70 mm. Hg, pulse rate 120, and respirations 28 per minute. Frequent tracheal suction was carried out with the use of a catheter and occasionally, a bronchoscope. At 1:00 p. m. corneal reflexes were present for the first time, and the deep tendon reflexes were hyperactive. Tests for bromides and barbiturates in the blood were negative. At 2:00 p. m. the patient began showing signs of voluntary activity. She was given 1,000 cc. of 10% dextrose solution intravenously. Bronchoscopy was performed at 6:00 p. m., and a large quantity of yellowish mucoid material was removed. At 11:10 p. m. she was showing more signs of voluntary activity, trying to get out of bed, coughing actively, and attempting to talk. By early morning of April 6, she was rational and admitted having taken a large quantity of barbituric acid, although the specific drug and the quantity taken were not determined.

CASE 2.—A 57-year-old man was admitted to the hospital in a comatose condition at 4:30 p. m. on May 17, 1950. He appeared pale, respirations were weak, and he could not be aroused. The urine contained barbiturates, although quantitative analysis was not done. Blood pressure was 100/60 mm. Hg, pulse 110, and respirations 44 per minute. He was placed in an oxygen tent soon after admission and was given 500 cc. of 5% dextrose in isotonic sodium chloride solution and 40 mg. of *amphetamine (Benzedrine) sulfate intravenously.* An additional 20 mg. of amphetamine sulfate was given intravenously at 7:00 p. m. The pulse seemed much weaker, and body temperature was 99.4 F rectally, pulse 100, and respirations 34 per minute. Respirations became more labored, and there was evidence of a large quantity of mucus in the tracheobronchial tree. Bronchial aspiration at 10:00 p. m. yielded a large amount of mucus. The patient was given 300 cc. (75 gm.) of salt-poor human serum albumin intravenously over a one hour period. At 11:30 p. m. 20 mg. of amphetamine sulfate was given intravenously. The pulse seemed somewhat weaker, and respirations were very shallow. At 12:00 a. m. body temperature was 99.4 F by axilla, pulse 128, and respirations 26 per minute. At this time, 500 cc. of blood plasma was given. At 1:30 a. m. color was slightly improved, and at 2:30 a. m. blood pressure was 105/68 mm. Hg and pulse 124. Respirations were still shallow. At 3:30 a. m. 1,000 cc. 5% dextrose in water was given intravenously. The pharynx and trachea were aspirated frequently by catheter. At 4:00 a. m. the body temperature was 100 F by axilla, pulse 122, and respirations 26 per minute. The patient was still not responding, although the cyanosis had cleared from his nail beds. At 5:30 a. m. the blood pressure was 118/70 mm. Hg and pulse 120. At this time the patient began moving his legs. At 8:00 a. m. blood pressure was 120/70 mm. Hg. He was moving his legs frequently, and his color was good, but he was still unconscious. *At 9:30 a. m. he began trying* to open his eyes, and his blood pressure was 120/68 mm. Hg. By 12:00 p. m. he was moving about in bed and appeared restless. By 4:15 p. m. the patient's respirations were regular and deep, and he appeared to be awake and responding, although he was very restless. He tried several times to get out of bed. At 10:00 p. m. he was taking liquids by mouth but was still unable to speak coherently. He seemed to com-

prehend well and obeyed commands. At 7:00 a. m. on May 19, the patient was rational and was asking for relief of pain. Body temperature was normal, pulse rate 100, and respirations 32 per minute. He continued to improve rapidly and was discharged on the fourth hospital day.

CASE 3.—A 49-year-old man was seen by his wife at 10:30 p. m. the evening before admission. At 9:30 the next morning she attempted to arouse him, but he did not respond. One and one-half hours later she tried again to awaken him without success. He was admitted to the hospital on July 30, 1952, at 3:00 p. m. Pentylenetetrazol (3 cc.) was given intramuscularly on admission. His wife reported that two bottles of amobarbital (Amytal) sodium had disappeared. On admission the patient appeared cyanotic and deeply comatose, with rapid, stertorous respirations. The skin was hot and the face and neck flushed. The eyeballs were fixed, and the pupils were 1.5 to 2 mm. in diameter; they did not react to light. Body temperature on admission was 103 F rectally, pulse rate 120, respirations 30 per minute, and blood pressure 120/70 mm. Hg. Bronchial breathing predominated. Heart sounds were muffled and partially obliterated by the breath sounds. Deep tendon reflexes and superficial reflexes were absent. The patient appeared to have barbituric acid intoxication (table 2).

At 12:30 p. m. the blood pressure was 142/95 mm. Hg. At 1:00 p. m. it was 150/100 mm. Hg, pulse 107, and respirations 30 per minute. At 1:30 p. m. the blood pressure was 165/105 mm. Hg, at 2:00 p. m. 200/80 mm. Hg, and at 2:30 p. m. it was 210/60 mm. Hg, with irregular pulse and increasing cyanosis. The intratracheal tube was removed and replaced, and the trachea was aspirated. Administration of picrotoxin was discontinued. At 4:00 p. m. his color was improved; the blood pressure had decreased to 100/58 mm. Hg, and the pulse was very irregular. The patient was beginning to move his arms and face. He was digitalized, receiving 4 cc. of lanatoside C (Cedilanid) intramuscularly at 9:00 p. m. At 10:30 p. m. he was restless and trying to sit up in bed. At midnight he was talking incoherently, asking for his wife, and insisted on going to the bathroom. He continued to improve and was able to eat a large lunch on Aug. 1. Digitalis was given for the next few days, and chloral hydrate was given in 15 grain (0.97 gm.) doses for sedation. The patient was discharged to a sanatorium on Aug. 8, 1952. During the acute episode of hypertension, when the systolic blood pressure had gone over 200, picrotoxin was withdrawn because of rapid irregular respiration. Electrocardiograms showed myocardial damage with apparent pericarditis.

SUMMARY AND CONCLUSIONS

The recovery phase in all three patients was similar. In cases 1 and 3 return of reflexes occurred at 23 and 17 hours respectively after serum albumin was given. Return of reflexes occurred eight hours after serum albumin was given in case 2. All of the patients showed signs of voluntary activity and return of consciousness within a few hours after return of the deep reflexes. There were no maniacal tendencies, and restraints were not required. This is in sharp contrast to the behavior of many patients recovering from barbiturate poisoning when the usual therapeutic agents are used.

Definite conclusions cannot be made from the study of three cases; however, the response to, and results of, the treatment were so uniform that further study seems warranted. This report is made with the hope that the use of analeptics will be abandoned in treatment of barbiturate intoxication. Treatment should be directed toward correcting the cerebral anoxia by eliminating cerebral edema through the use of salt-poor serum albumin or some other agent that will accomplish the same result by action of its high osmotic pressure in drawing the intracellular fluid back into the circulation. General supportive treatment such as adequate oxygen and fluid therapy is essential, and measures should be taken to lower body temperature in patients who have hyperthermia.

803 Summit Ave.

SULFOBROMOPHTHALEIN CLEARANCE TEST

Raymond D. Goodman, M.D.
and
George R. Kingsley, M.S., Beverly Hills, Calif.

One of the most frustrating experiences facing the clinician today is the study of liver function. Since several excellent reviews on this subject appear annually, there is no need to recount the extensive literature in this report. It is conservative to say that the liver is probably involved in more physiologically different processes than any other organ in the body; thus, it is exceedingly difficult to designate any single test as "the" indicator of liver function. Even the liver biopsy, which is a valuable tool in the identification of liver disease, cannot serve as sole index to liver functions. Microscopic analysis indicates whether the structure appears normal or abnormal, but in neither case can it reveal to what extent the function of this structure is altered. In an attempt to obtain a quantitative assessment of liver function, we described, in a previous publication, a modification of the sulfobromophthalein (Bromsulphalein) excretion test based on the measurement of sulfobromophthalein clearance.[1] The purpose of this report is (1) to introduce several improvements in the procedure and (2) to summarize our experiences in a significant number of cases.

METHOD

Prerequisite Conditions.—The patient must meet the following requirements. He must have been in a fasting state for 10 hours, have no fever and no jaundice (icteric index less than 20 units), and be in a supine position during the test.

Procedure.—There are seven steps in the procedure. 1. Weigh and record the weight of patient in kilograms. 2. Draw and exact volume of sulfobromophthalein solution to the nearest 0.1 ml. of dye solution (50 mg. per milliliter) into a sterile 10 ml. syringe so that the injected dose will be 5 mg. per kilogram of body weight. 3. Inject

Dr. J. V. Monke aided in the study of group 2, and Mrs. Louise Wollin helped prepare the manuscript.

[1] Goodman, R. D.: Bromsulfalein Clearance: A Quantitative Clinical Test of Liver Function, J. Lab. & Clin. Med. 40: 531-536 (Oct.) 1952.

the sulfobromophthalein intravenously at a constant rate (injection should require about 30 seconds) and start timing the test when half of the dose has been given. A stop watch is preferred, but the sweep second hand of an ordinary watch may be used. Let the stop watch continue to run. 4. At approximately five minute intervals after the injection, withdraw 5 ml. samples of blood, transfer them quickly to 120 by 12 mm. test tubes and allow the blood to clot. Do not force blood through needles; do not add blood foam with the sample to the test tube; and do not shake the tubes. Hemolysis must be avoided. 5. For accurate timing, compute the mean time of blood samples according to the following schedule:

Start	Stop	Mean Time
5′ 10″	5′ 30″	5′ 20″
10′ 15″	10′ 30″	10′ 23″
14′ 25″	14′ 38″	14′ 32″

Starting time should coincide with appearance of blood, stopping time with the end of withdrawal.

Four samples should be used, and they should be taken at approximately 5, 10, 15, and 20 minutes (all within the first 20 minutes). 6. Add 0.5 ml. of cell-free serum, which has not hemolyzed, after centrifugation from each sample taken after dye injection to photometer tubes, each containing 5 ml. of 0.1 N sodium hydroxide; mix this. Also, in order to prepare blanks, add 0.5 ml. of serum from each sample to photometer tubes, each containing 5 ml. of 0.1 N hydrochloric acid. Set the photometer at 100% transmission. The dye concentration is calculated from the optical density of the test solution at 575 mcg. light transmission. A Coleman Junior spectrophotometer was used in this study. 7. plasma dye concentration is plotted against time in minutes on a two cycle semilog graph, and the result is obtained by following the steps indicated in figure 1.

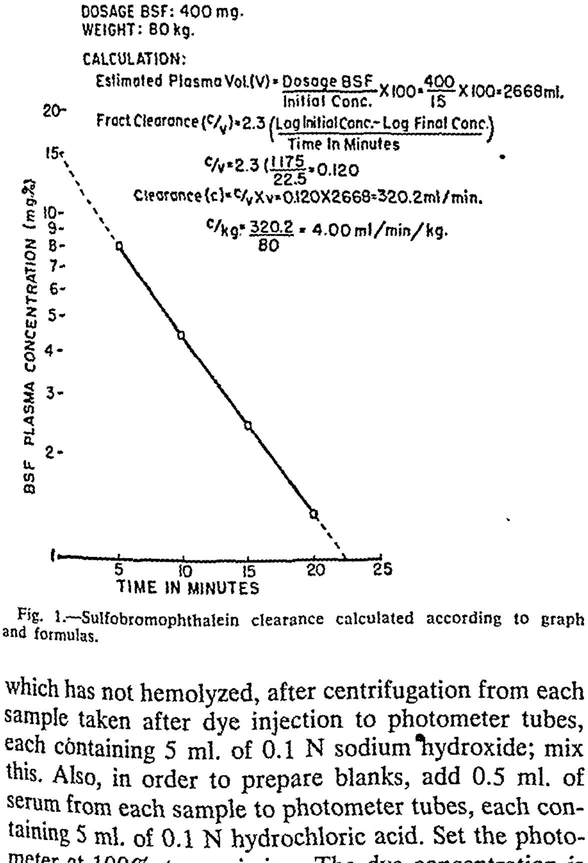

Fig. 1.—Sulfobromophthalein clearance calculated according to graph and formulas.

Standardization.—The method is standardized by diluting 0.5, 1, 2, 3, 4, and 5 ml. of a stock dye standard (0.1 ml. of 5% dye solution from Hynson, Dunning, and Wescott ampul diluted to 500 ml. with 0.1 N sodium hydroxide) to 5 ml. with 0.1 N sodium hydroxide solution. Add 0.5 ml. of normal pooled serum to each tube and mix. Prepare a blank by adding 0.5 ml. of normal pooled serum to 5 ml. of 0.1 N hydrochloric acid and mix. Set blank at 100% transmission with light transmission at 575 mcg. Record transmission of each dilution and make a table for conversion of the per cent transmission to milligrams of dye per 100 ml. of serum.

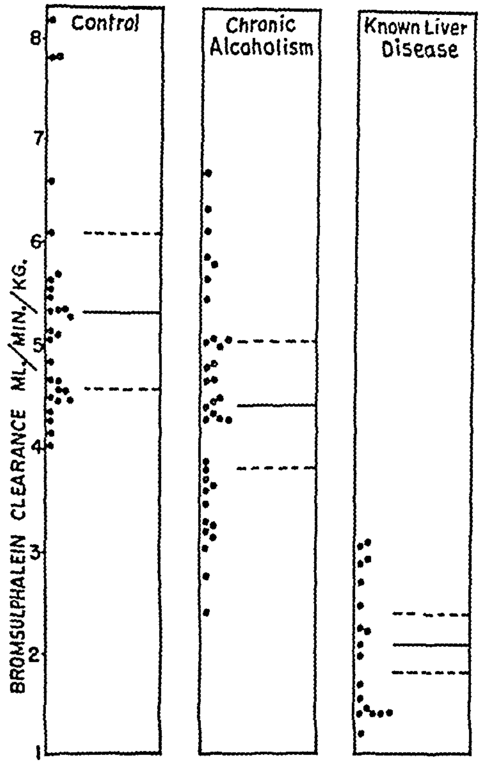

Fig. 2.—Results of sulfobromophthalein clearance tests in three groups of patients.

SELECTION OF PATIENTS

All of the patients included in this study were men in a large general hospital. They were divided into three categories according to certain specifications. Those in group 1 had no history or clinical evidence of liver disease at any time and no history of chronic alcoholism or other contact with hepatotoxic agents. Those in group 2 had a history of chronic alcoholism; no history or clini-

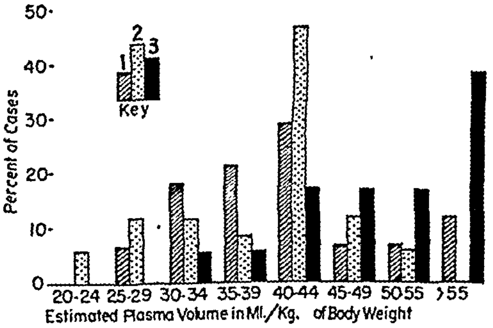

Fig. 3.—Comparison of values for estimated plasma volume found in three groups of patients.

cal evidence of liver disease at any time; no history of recent acute alcoholism; and good nutritional status for several weeks prior to testing. Those in group 3 had known liver disease, either past or present. Ten of the 18 patients in group 3 had liver biopsies confirming the clinical diagnosis.

All of the patients were hospitalized and received thorough medical examinations, including routine blood and urine tests. Group 1 consisted chiefly of convalescent patients from the medical service. These patients had recovered from their initial complaints and were nearly ready for discharge. Group 2 consisted entirely of patients from the neuropsychiatric service. They were hospitalized for disulfiram (Antabuse) therapy and rehabilitation. Group 3 consisted mainly of patients in different stages of cirrhosis of the liver, irrespective of etiology.

RESULTS

The data on 81 patients appear in tables 1, 2, and 3. Wherever possible, additional tests of liver function were obtained, namely, icteric index, prothrombin time, albumin-globulin ratio, cephalin-cholesterol flocculation, thymol turbidity, thymol flocculation, and liver biopsy. In addition, an estimate of the plasma volume was made in each test, since it can be computed from this technique. The data on sulfobromophthalein clearance are graphed in figure 2. The solid horizontal line in each column represents the mean value, while the broken horizontal lines indicate the standard deviation from the mean. Figure 3 shows the range and distribution of estimated plasma volume determinations made by this procedure.

The separation of groups 1 and 3 is clearly evident (fig. 2). All of the values in the control series yielded values above 4 ml./min./kg., while nearly all the values in the group with liver disease fell below 3 ml./min./kg. Group 2 is of special interest because 37% of the values fell below 4 ml./min./kg., and prior to testing there was no reason to expect such results. In group 3, it is of further interest to note that the eight patients who did not have liver biopsies nevertheless had sulfobromophthalein clearance values within the same range as those who had confirmatory biopsies. The data on estimated plasma volumes for groups in which no liver disease was evident showed essentially a normal distribution about the mean (40 ml./kg. of body weight); a much higher plasma volume was consistently found for patients having liver disease.

COMMENT

The advantages of this test over the conventional 45 minute sulfobromophthalein retention test have been described previously.[1] The value of any clinical laboratory test depends on its safety, reliability, simplicity, reproducability, and economy. Enormous quantities of sulfobromophthalein have been used in the past 25 years with reportedly few toxic effects. No unpleasant reactions were observed in any of our patients. The data on clearance correlate well with the clinical observations made in this study. We have shown in both controls and persons with chronic liver disease that the clearance test can be repeated in 24 hours, one week, or two months and still give a check within 5% of the original value. The same observations were made by earlier investigators who were studying sulfobromophthalein excretion rates. Through the past two decades many chemical tests of liver function have been discarded, but the sulfobromophthalein test has remained a favorite of many.

The clearance test is, indeed, simple. It requires no expensive reagents or complicated laboratory procedures. Twenty minutes of the examiner's time is far less than that required for the ordinary tolerance tests. Even the mathematical computation has been condensed into a formula that any trained technician can readily solve.

The clinical data from this study require very little discussion. We have expressed liver function quantitatively in a manner that provides a clearcut separation between our controls and those with liver disease. The fact that alcohol is a predisposing, if not causative, agent in the production of liver injury is certainly supported by the results in group 2.

We also want to emphasize that in each case studied an estimate of plasma (or serum) volume was made by conventional dye dilution procedures. The arbitrary use of a universal standard such as 40 or 50 ml. per kilogram of body weight is bound to engender greater sources of error. Our knowledge of liver disease, for example, has already revealed by other methods that the extracellular compartments undergo drastic changes from the normal state. It seems only reasonable, therefore, that a direct measurement of the plasma volume be made in each person studied by clearance techniques.

SUMMARY

Sulfobromophthalein (Bromsulphalein) clearance determinations were made in 81 patients. The control group had a mean value of 5.33 ± 0.75 ml./min./kg. All of the values for the control group were above 4 ml./min./kg. The group of patients with definite liver disease had a mean value of 2.06 ± 0.30 ml./min./kg., and no value was above 3 ml./min./kg. The patients who were chronic alcoholics had a mean value of 4.45 ± 0.63 ml./min./kg. Although this mean was only slightly less than that of the control group, 37% of the values were below the lowest value obtained for any of the controls.

This test is safe, simple, rapid, and reliable and gives more information than previously reported modifications of the sulfobromophthalein test. The added value of using sulfobromophthalein disappearance to estimate the plasma volume deserves further consideration and investigation. We do not wish to imply that this test is the best test of liver function, since it is doubtful that there will ever be a single test to rely on. We have been encouraged by our results and hope that others will be stimulated to adopt this technique.

NATAL DAY DEATHS

THE LONG-NEGLECTED FIELD OF INFANT MORTALITY

Herman N. Bundesen, M.D., Sc.D., Chicago

Our recent 14-year study of 10,000 neonatal deaths with satisfactory postmortem examinations and complete clinical investigations indicates that too many infants continue to die needlessly, especially during the critical early days of life. We are still doing too little, too late, and not too well for too few in the long neglected field of infant mortality. That is why the present level of early infant deaths still presents a major problem. Those responsible for this failure to reduce early infant mortality include health officers, obstetricians, pediatricians, hospital administrators, and all others concerned with the care of the pregnant woman and her newborn infant.

The task that confronts the health officer, whose duty it is to contribute to a reduction in the number of needless infant deaths, is to plan a definite program aimed specifically at reducing the number of such deaths in the areas in which they are most frequent and to see that this program is put into action and carried out to the letter. Such a program, to be most effective, should be planned and carried out in cooperation with physicians, hospital administrators, and nurses.

Before the health officer can plan and put this cooperative program into action, he must adopt the following procedures: 1. He must carefully analyze and evaluate all infant deaths occurring within his jurisdiction, to determine the age and weight groups in which most of them occur. 2. He must make every effort to see that the causes of death as given on the death certificates are the true anatomic causes. 3. He must determine from such correct certificates the most frequent actual causes of death and by investigations find the factors contributing to the deaths in the age and weight groups in which the majority are occurring. 4. He must reanalyze and audit his existing plan for controlling infant mortality and, in the light of these analyses, determine wherein it is failing to produce results, so that it may be altered accordingly. 5. He must vigorously and aggressively make his plan operative and keep it operative once he has adopted it.

This type of program has been instituted in Chicago, and it has been found that over half of all infant deaths (52.0%) now occur within the first three days of life—more than on the other 362 days of the first year combined. More than half of these early deaths (53.2%) occurred in infants with a birth weight under 1,500 gm. In Chicago, the great majority of neonatal death certificates now do carry the accurate anatomic cause of death. because postmortem examinations are performed in over 85.0% of these deaths. These accurate death certificates, but more particularly a study of satisfactory postmortem examinations,[1] have shown that almost three-fourths (70.0%) of the early deaths occurred from just two causes, abnormal pulmonary ventilation (respiratory distress) and injuries at birth.

It is these early deaths that comprise the long-neglected field of infant mortality, and it is in this field particularly that the Chicago Board of Health's plan for reducing mortality has failed to produce the desired results. After reanalyzing our existing plan, we have found that it did not produce the desired results because of two types of failures: 1. We concentrated our efforts

---

President, Chicago Board of Health.

Read in the Symposium on Prevention of Needless Neonatal Deaths before the Section on Pediatrics at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

[1] To be considered satisfactory, a postmortem examination (1) must be done by a competent pathologist, familiar with fetal and infant disease, (2) must include a gross examination of the entire body including the brain and cranial cavity, (3) must include a microscopic examination of any tissues necessary to make an accurate diagnosis, and (4) must include a complete report of the results of the examination. Whenever the postmortem record stated that microscopic examinations of all important tissues were not made, but the cause of death was obvious to the trained pathologist from the examination made, the postmortem was also considered satisfactory.

neither on the deaths in the low weight groups nor against the two commonest causes of early deaths, abnormal pulmonary ventilation and injuries at birth. 2. Although we had formulated regulations for maternity divisions and newborn and premature nurseries, these regulations did not provide for constant and consistent optimal care for mothers and their infants. Moreover, we failed to enforce to the letter the regulations we had.

Frankly, in retrospect, we now realize that self-satisfaction with what we had already accomplished diverted attention from the long-neglected field of infant mortality, and thus we did not make progress in reducing the number of early infant deaths. Thus, from 1935 to 1946, a period in which comparable figures of other cities were obtainable, the infant mortality of Chicago was the lowest among the now 10 largest cities in the United States; however, from 1941 to 1946, the rate for Chicago remained almost static but still was lowest among the 10 largest cities. After 1941, the infant death rates in most of the other large municipalities continued to decline gradually and finally reached about the same level as that of Chicago, although the rate in Chicago for the combined period from 1940 to 1950 is lower than that of any of the 10 largest cities in the United States (table 1).

TABLE 1.—*Comparison of Births, Infant Deaths, and Infant Mortality for the Ten Largest Cities in the United States from 1940 to 1949**

City	No. of Births	No. of Infant Deaths	Combined Infant Mortality
Chicago	691,519	19,645	28.4
New York	1,351,608	39,148	29.0
Los Angeles	368,713	11,017	29.9

St. Louis	172,475	6,008	34.8
Philadelphia	389,818	14,060	36.1
Boston	158,781	5,850	36.8
Baltimore	204,632	7,940	38.8
Washington, D. C.	177,677	7,225	40.7

* Data were taken from the annual reports "Vital Statistics of the United States" published by the National Office of Vital Statistics, Federal Security Agency, United States Public Health Service, for the years 1940-1949.

Since by 1950 we had become too complacent about our then low infant death rate we did not investigate carefully when and why so many of our smaller infants were continuing to die. Although we had completed our study of 10,000 neonatal deaths, we failed to interpret properly the facts that this study revealed. We failed to take cognizance of the high mortality among the very small infants dying perinatally (just before, during, or immediately after birth) and particularly during the first three days of life and, therefore, made little effort to reduce this high rate. We were misled by failure to subdivide the deaths of the neonatal period into more restricted groups. Therefore, it took us too long to carefully analyze and then use all the actual facts about the specific delimited group of natal day deaths. Since we did not have these facts, we could not attack the problem of these deaths at the points where most of the attack should have been centered.

Just as up to 1935, in attempting to control deaths at various ages, there was too much stress on reducing infant mortality and too little on reducing neonatal mortality, so now there is too much stress on neonatal mortality and too little stress on natal day mortality, or better still on deaths during the first three days. Up to 1938, we based our preventive efforts on the inaccurate causes of death as shown on the ordinary death certificates without a satisfactory postmortem examination, just as most health officers did and as many still do. In 1935, we began our study to determine the actual anatomic causes of death as revealed by our satisfactory postmortem examinations. By 1938,[2] we were fully convinced that the causes given on most death certificates were inaccurate and misleading and hence were misguiding health officers in their preventive efforts. As early as 1938, we were beginning to recognize that the two main causes of death against which preventive efforts had to be exerted were abnormal pulmonary ventilation (respiratory distress) and injuries at birth. Nevertheless, we failed to take action against deaths from these two causes in the early age, low weight groups. Many of these deaths could have been prevented by early aggressive corrective action in providing the best possible prenatal care of the mother, natal care of the mother and infant, and immediate postnatal care of the infant.

In the control of infant mortality the greatest effort must be concentrated on the groups in which most of the deaths are occurring. It predicates that infant mortality has become static because insufficient preventive efforts have been exerted toward the age, weight, and known cause of death groups, in which most deaths occur.

For some years now every neonatal death has been investigated in Chicago, and it has been found that far too many were preventable during the first day of life. The major causes of these needless deaths and the problems of their prevention differ markedly from those during the remainder of the first month. Because of this fact, it has been felt essential to separate the deaths on the first day from those in the remainder of the first month, and the deaths occurring on the first day of life are called natal day fatalities.

NATAL DAY MORTALITY

Based on data on 10,000 neonatal deaths, the greatest problem confronting those interested in reducing infant mortality today seems to be to determine what preventive efforts should now be directed primarily toward reducing natal day mortality. Actually, during 1952 in Chicago, over one-third (35.6%) of all infant deaths occurred on the critical natal day.

We believe that a significant reduction in infant mortality rates could be effected by making an intensive attack on the causes of deaths that occur during the first hour, the first eight hours, the first day, and the first three days of life. For example, in Chicago, in 1952 the deaths of infants in the first hour after birth represented 27.2% of the deaths of the first eight hours, those during the first eight hours represented 66.5% of the deaths on the first day, those on the first day represented 68.4% of the deaths of the first three days, and those on the first three days represented 73.1% of the deaths of the first 28 days and 52.0%, or more than half, of the deaths of the first year.

---

[2] Bundesen, H. N., and others: Factors in Neonatal Deaths, J.A.M.A. 111:134-141 (July 9) 1938.

A comparison of Chicago rates in 1912 with those in 1952, which are similar to those in many other parts of the United States, shows that during the last 40 years there has been practically no reduction in the mortality of the first day of life (fig. 1). For example, in 1912, the death rate for the first day of life was 11.1 per thousand live births. By 1952, the natal day death rate was 9.4, a reduction of less than two for every thousand live births. On the other hand, the death rate in 1912 for infants dying during the first month of life (*neonatal*[3] *death* rate) was 46.2 per thousand live births. By 1952, it was 18.9, a reduction of 27 for every thousand live births, most of which reduction was in deaths occurring after the first week. Even more startling is the fact that the death rate in 1912 for infants dying during the first year of life was 118.6 per thousand live births. By 1952, it was 26.4, a reduction of 92 for every thousand live births, most of which reduction was in deaths occurring after the first month (fig. 1). During these 40 years, in Chicago as almost everywhere else, there has been a great reduction in the death rate under 1 year (nearly all of which was in the period 1 through 11 months), about one-third as much reduction in the death rate under 1 month, but, by comparison, practically none in the death rate under 1 day.

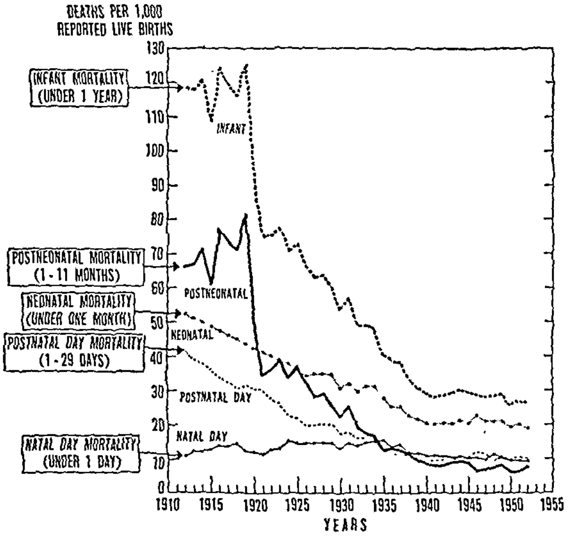

Fig. 1.—Infant, postneonatal, neonatal, postnatal day, and natal day mortality in Chicago, 1912-1952.

In 1934, the natal, postnatal, and postneonatal death rates per thousand live births reached the same level, because postnatal and postneonatal deaths were declining while the natal day death rate was remaining constant. Moreover, since 1934, these two rates have continued to decline, so that the natal day deaths have become an ever-increasing proportion of the total infant deaths, and now in 1953 natal day deaths are the major pressing problem in the control of infant mortality. In 1912, the natal day deaths comprised only 1/10 of the total infant deaths, while in 1952 they comprised over 1/3 of these deaths. Over a 40 year period natal day fatalities (under one day) have been reduced only 1/53 as much as the infant deaths (under one year) and only 1/15 as much as neonatal deaths (over one day).

CLASSIFICATION OF FATALITIES INTO AGE GROUPS

In the last 40 years most health officers seem to have overlooked the full significance of the large number of preventable deaths occurring on the first day of life. This has come about largely because the usually acceptable age group classification of deaths of "under 1 month" and "under 1 year" is grossly misinforming and thus misleading. It is misinforming because all deaths under 1 month are grouped together even though the rate of death on the various days of the neonatal period differ greatly, the birth weights of the infants dying during the various parts of the neonatal period also differ to a great extent, and the causes for the deaths during the various parts of the neonatal period are different to a great degree. Therefore, to be accurate and informative it is necessary to classify neonatal deaths in four age groups, depending on the weight groups in which most of the deaths occur and the causes for all deaths.

On this basis, our studies have convinced us that neonatal deaths should be classified into four groups, namely, deaths that occur during the first day, during the first three days, during the first week, and during the period 7 to 27 days, inclusive, instead of just into one group of under 28 days, as is now done. Therefore, we have classified the neonatal deaths in our series in these four age groups, and we have labeled them with what we believe to be definite, descriptive terms as natal day deaths (first day), tridiem deaths (first 3 days), hebdomadal deaths (first week) and posthebdomadal deaths (7 to 27 days). In studying these deaths we have classified them by age, weight, and cause, and not just by age or weight or cause alone.

The percentage distribution of our accurate seven causes of death in age periods show that our classification by age groups and cause of death is a logical one and clearly shows the direction in which our preventive efforts may be most effective (table 2). It will be noted from this table that, during the first day and the first three days, the proportion of deaths from abnormal pulmonary ventilation and injuries at birth combined far exceeds that of all other causes of death. During the balance of the first week (three to seven days), the proportion of deaths from abnormal pulmonary ventilation decreases materially, whereas the proportion of deaths from infection and blood dyscrasias combined increases directly with age. In the distribution for the posthebdomadal deaths (after the first week), infections and malformations become the leading causes of death, while abnormal pulmonary ventilation and injuries at birth decline (fig. 2).

A sensible classification of infant deaths into more delimited age groups by cause of death (and by weight as well), when the causes are determined by satisfactory postmortem examinations, will make the figures especially informative. Then, when all concerned utilize this informative classification with identical criteria and base lines, they will become aware of the actual causes of death in the various age and weight groups against which preventive measures are needed in their areas and may then logically and successfully apply them. Furthermore, these similar data from states and local areas can then be combined so that a mass of statistically significant data will be available for analysis by everyone concerned.

---

[3] The definition of the World Health Organization for neonatal is the period under 28 days.

The majority of all natal day deaths occur in smaller infants weighing less than 1,500 gm. (3 lb. 5 oz.) at birth. It is important here to stress that in our classification prematurity per se was not considered to be an actual cause of death because, in the light of present knowledge, prematurity is only a measure of the length of uterogestation.

All infants prematurely born, irrespective of weight, account for only 8.1% of all the live births, but they account for 79.1% of all the natal day deaths. However, lower weight infants (under 1,500 gm. at birth) comprise only 1.3% of all live births, but comprise 60.1% of all the natal day deaths. Moreover, among these premature infants of lower weight, 704.0 died during the first year for every thousand born. Conversely, heavier weight infants (2,000 to 2,500 gm.) comprise 5.4% of all the live births, but they comprise only 7.4% of all the natal day deaths. Moreover, among the premature infants of heavier weight, only 53.4 died for every thousand born.

TABLE 2.—*Anatomic Causes of Infant Deaths in Chicago 1936-1949*

	Percentage of Total No. of Infants Who Died at Various Ages by Cause									
Condition	Under 1 Day	Under 3 Days	1 to 3 Days	Under 1 Week	3 to 7 Days	8 to 29 Days	3 to 29 Days	1 to 29 Days	Under 30 Days	1 to 11 Months
Abnormal pulmonary ventilation	54.3	50.2	50.6	47.5	28.2	16.3	22.4	21.4	43.7	6.8
Injuries at birth	18.2	18.8	19.1	18.3	13.3	4.4	9.3	9.3	16.6	1.3
Malformation	12.0	12.5	12.1	13.5	22.4	32.1	26.9	19.8	15.8	19.7
Infections	6.2	8.7	8.4	10.0	20.5	38.3	28.8	35.7	13.4	55.6
Blood dyscrasias	3.9	4.7	4.7	5.5	10.4	3.9	7.2	4.3	5.3	0.9
Anoxia	4.7	4.4	4.4	4.2	2.9	0.9	2.0	1.6	3.8	0.0
Miscellaneous	0.7	0.7	0.7	1.0	2.3	4.3	3.4	7.8	1.4	15.7

In the past much effort and personnel has been led in the wrong direction because of the misleading term premature, just as up to the present the term neonatal has been misleading. When all premature infants are subdivided into a number of significant weight groups, instead of being classified in just one weight group (5 lb. 8 oz. and under) as required by definition (World Health Organization), efforts at controlling mortality among them can be more efficiently applied because of the following proved facts: 1. Deaths in smaller premature infants often result from different causes than deaths in larger premature infants. 2. Specialized care immediately after birth is required for the smaller premature infant, while relatively little care is required for larger premature infants. 3. Nonwhite infants between 2,350 and 2,500 gm., who make up 12% of all premature infants, must be classified as premature infants on the basis of the definition of prematurity by weight alone (5 lb. 8 oz. and under). In reality, on the basis of ossification centers [4] and other grounds, they are physiologically full term and are not regarded as premature by many authorities.[5] In Chicago, in 1952, 12.7% of all nonwhite infants were premature, while only 6.7% of all white infants were premature. If nonwhite infants with a birth weight between 2,350 and 2,500 gm. were not considered to be premature, nonwhite premature births would have been only 8.6% of all nonwhite births. I believe that this figure of 8.6% is a truer representation of the frequency of premature births among the nonwhite than is the figure 12.7%.

When regulations [6] for the control of maternity divisions and newborn nurseries covering policies, personnel, procedures, and equipment were first formulated in 1937, the same type of intensive, continuous care was required for all premature infants irrespective of whether the infant was large or small and the strict requirements of these regulations were aggressively enforced. As a result, the efforts of trained scientific personnel were unnecessarily scattered over too wide a range, providing special care for many infants who did not need it to the neglect of such care for the lower weight group where it was desperately needed. It is those smaller infants who accounted for 60.1% of the natal day mortality and 53.2% of the tridiem mortality.

CAUSES OF DEATH IN THE EARLY AGE AND LOW WEIGHT GROUPS

There are seven major anatomic causes of death in the neonatal period, according to our classification, namely: (1) abnormal pulmonary ventilation, (2) injuries at birth, (3) malformations, (4) infections, (5) blood dyscrasias, (6) anoxia, and (7) miscellaneous causes. Our recent study showed that abnormal pulmonary ventilation and injuries at birth alone account for 72.5% of all the infant deaths that occur during the first day of life, of which abnormal pulmonary ventilation causes 54.3% and injuries at birth cause 18.2%. These two causes are responsible for 83.5% of all the deaths on the first day in infants of low weight (under 1,500 gm.). It is on the basis of these facts about the frequency of these two main causes of early infant deaths that we predicate much of our action to reduce needless perinatal deaths. Abnormal pulmonary ventilation includes all those infants who, on satisfactory postmortem examination, show no specific pathological lesions except those that may be in the lungs. In many instances, the deaths from abnormal pulmonary ventilation are due to the anatomic condition known as abnormal pulmonary ventilation with hyaline-like membrane and resorption atelectasis. In some instances, the deaths are due to extreme immaturity of the lungs. Occasionally, no cause could be demonstrated other than varying degrees of atelectasis (respiratory distress), in which deaths could be accounted for only on the basis of inadequate functioning of the lungs.[7]

[6] The Joint Maternal Welfare Committee of Cook County aided in the formulation of the regulations.

The category "injuries at birth" includes mainly those infants who die from intracranial hemorrhages. Nineteen per cent of the deaths in the first three days of life are due to injuries at birth. Our study revealed that a total of 56.7% of the neonatal deaths due to injuries at birth in Chicago were infants that were premature, and the majority of these occurred on the first day of life. We also found that the method of delivery is by far the most important of all the factors related to these deaths. Hence, it is evident that the most skilful type of obstetrics in delivery of the premature infant is needed to help reduce the number of deaths in these infants from intracranial hemorrhage.

In the established classification of causes of death, which is set up by the World Health Organization and followed by the National Office of Vital Statistics, based only on the statement of the cause as shown on the death certificate, most deaths in premature infants are grouped together regardless of the weight of the infants and the true anatomic cause of death. They are erroneously charged to prematurity, although the actual cause of death is not prematurity per se but rather abnormal pulmonary ventilation or injuries at birth. Prematurity is a measure of gestation, although by definition (World Health Organization) it is a weight (5 lb. 8 oz. and under). On the basis of our postmortem examinations, we do not believe that prematurity can be classified as a cause of death.

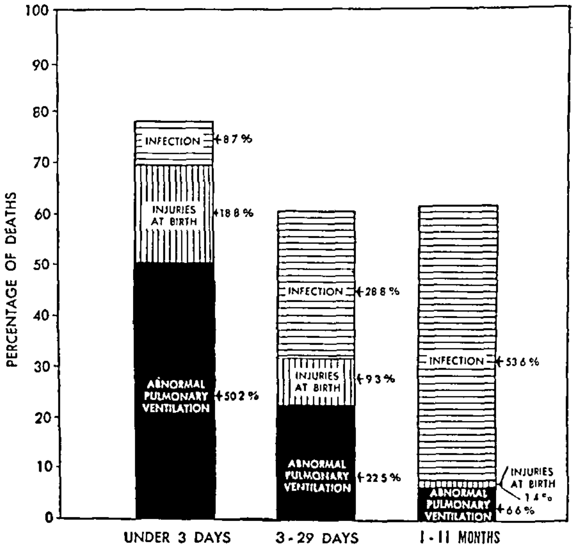

Fig. 2.—Percentage distribution of three main causes of death among infants by age at death, in Chicago, 1936-1949. With increasing age during the first year, deaths from abnormal pulmonary ventilation and injuries at birth decreased proportionately and infections increased, so that for the period 1 to 11 months more than half of the deaths were due to infection and only a small portion due to injuries at birth and abnormal pulmonary ventilation.

To group all premature deaths together is just as illogical as it would be to group together all deaths during the neonatal period and erroneously charge them to a useless definition such as "neonatality," which literally means dying of "young age," just as we now say persons die of old age. Rightly, we charge these neonatal deaths to the specific conditions causing them, such as infections or malformations. Yet, officially[8] we are required to group together all deaths in premature infants and erroneously charge them to a definition or a word "prematurity" instead of to such actual causes of death as abnormal pulmonary ventilation or injuries at birth.

With good obstetric and pediatric care, many premature infants who die could live. But when deaths are erroneously charged to prematurity, many may exert all their efforts in the prevention of prematurity with too little consideration of the painstaking care that the obstetrician must utilize in delivery of these infants and the special pediatric care required immediately after birth. These deaths in premature infants depend, in many cases, on lack of the best possible obstetric (prenatal and natal) and pediatric (postnatal) care on the part of everyone concerned, the mother herself, the physician, the hospital administrator, and the health officer.

It must be borne in mind that, in the light of present knowledge, little is known about preventing prematurity in many cases, although there is much that the good obstetrician can do in this regard if the available knowledge were utilized. In the more informative classification used by us, deaths in premature infants are charged to the specific condition causing the death, such as respiratory distress, injury at birth, or infection. Guided by our classification, it is possible to better determine the kind of preventive measures that physicians, hospital administrators, nurses, and all others responsible for the care of these infants should utilize. This is not possible with the misleading classification of the National Office of Vital Statistics, which all state health officers and many others, including us, are required to use.

RESPONSIBILITY

From our past failures, we now realize that the health officer's function in reducing the number of early deaths in infants is to devise control measures that will be thoroughly, constantly, and specifically directed at improvement in the prenatal care of the mother and in the perinatal care of the mother and her infant. Our analysis of 10,000 neonatal deaths has demonstrated that, of the many prenatal and perinatal factors that have an effect on mortality rates of the first 3 days, five have a most profound influence. Two of these, socioeconomic status and the toxemias of pregnancy, are subject to prenatal control; the other three, method of delivery, anesthesia, and the type of care the infant receives, are subject to perinatal control. It is self-evident that efforts to control perinatal mortality must be applied mainly in the hospitals, because the great majority of infants are born in hospitals (96% in Chicago and 85% of the 3,900,000 births in the United States). Furthermore, of the deaths that occur during the first week (63% of all infant deaths in Chicago), the overwhelming majority (96%) occur before the newborn infants ever leave the hospital.

Our regulations for maternity divisions and newborn and premature nurseries were formulated for the purpose of improving the quality of these hospital services. We believe that the unsatisfactory conditions that have been found to exist in certain institutions with unnecessarily high death rates occurred because our regulations were not constructed so as to assure constant and consistent optimal care for mothers and their infants, and because we failed to enforce to the letter the regulations that we had. Our regulations were not formulated to differentiate between the care required for the lower weight and heavier weight infants. They did not take into account the need for the highest quality of administrative leadership on which depends the efficient functioning of all personnel in the maternity division and newborn nurseries. Because we failed to enforce the regulations that we already had in many important aspects, several unsatisfactory events resulted.

[8] Sixth Revision of the International Cause of Death Code of the World Health Organization. Vol. 1 and 2, World Health Organization, Columbia University Press, New York, 1948.

Policies and procedures in some hospitals were established on paper only and were not carried out, thus misleading the hospital administrator, physicians, nurses, and the health officer. Delivery of complicated cases was often entrusted to physicians not equipped to carry them out satisfactorily. The care of newborn and premature infants was all too often left to unqualified scientific personnel, and consultation was not immediately called when needed for desperately ill infants. Anesthetics were often administered by unqualified personnel, particularly at night, on Sundays and holidays, and in emergencies. Deaths actually resulted from improper administration of the wrong anesthetics. Many hospitals failed to meet the minimum requirements for adequate care and essential facilities; there was a shortage of medical and nursing personnel; and there was a lack of well-formulated policies. Faulty procedures in the labor and delivery room and newborn and premature nurseries at times existed to the degree of constituting real hazards to parturient mothers and infants. There was often a lack of sufficient space for maternity and nursery activities. There was a lack of joint free and frank discussions among all groups of personnel connected with the prenatal and parturient aspects of the care of the mother and the postnatal care of the infant. There was a lack of liaison among all those interested in the problem of providing adequate care for the mother and her newborn infant, including physicians, nurses, nutritionists, social workers, and the health officer.

The health officer who by ordinance is entrusted with the licensing and control of hospitals has the opportunity as well as the responsibility of making sure that all available knowledge and skill are utilized in the care of mothers and infants in these institutions. He can aid the hospital administrator in making sure that hospitals have available at a moment's notice all the essentials for providing proper care, including established policies, adequate personnal, proper procedures, and sufficient paraphernalia (equipment).

Through the establishment of an evaluation and rating system similar to those that have been utilized successfully in the control of dairies and restaurants, the health officer can help keep the hospital administrator informed of the exact conditions in his institution. We have found that with such a system, and with adequate well-trained inspection personnel, it is possible to determine closely in what respects each institution is deficient and actually to evaluate a hospital on its degree of compliance with the regulations. Even more important, with this system, it is possible to determine the quality of service the hospital is rendering to mothers and infants and many of the reasons why many infants died. When deficiencies are noted in a hospital, the health officer, by consultation with the hospital administrator and the chiefs of the obstetric, pediatric, and nursing staffs, can, as a rule, aid them in bringing about the necessary corrections. In the evaluation and rating system that we employ, the greatest weight is given to the quality of the personnel. Experience has shown that in those institutions where scientific personnel are well trained, are thoroughly skilled in what constitutes optimal care of the mother and her infant, and, above all, are imbued with an innate enthusiasm about the job they are doing mortality is at the lowest obtainable level. And conversely, in institutions where these conditions do not exist, where personnel is lackadaisical and more interested in extraneous activities than in providing optimal service, mortality does not decline but continues to ascend.

The health officer, in cooperation with the physician and the hospital administrator, by doing his full duty, can bring about improvement in policies, personnel, procedures, and facilities. He can do this primarily by aiming his efforts at making sure that leadership in the hospital as a whole and in each section of the maternity division is forceful, energetic, and endowed with a determination to make inroads on the number of needless deaths in the institution. Ultimately, it will be discovered that the type of care furnished by the hospital depends on top level administrative, obstetric, pediatric, and nursing leadership. When leadership is efficient, the hospital administrator, the physician, and nurses jointly assure that the training of all personnel is adequate and that they will continue to carry out their tasks without interruption. On this top level leadership also depends whether or not faulty procedures will be tolerated or obviated.

It is reliably estimated that some 85% of mothers deliver their infants normally without complications, but when complications occur requiring operative delivery, skilful technique is a requisite if the hazards to the infant are to be reduced to the minimum. Equally important is the knowledge of understanding what not to do, as well as what to do, for unnecessary interference in the birth processes, either by medication, operation, or anesthesia, often results in the loss of infant lives. Hence, "the desirable attendent for a pregnant woman is a physician adequately trained and experienced in obstetrics and, above all, so aware of his limitations, that, when emergencies arise which are beyond his competence, he will not delay in securing help." [9] The health officer, with the aid of the conscientious hospital administrator, can require proper organization of the maternity division of each hospital, so that well-qualified consultants are always available and are called when needed.

The chances of survival of any infant, especially the premature one, are reduced by the use of any type of analgesia and anesthesia during labor and delivery. The health officer has a responsibility in seeing that well-qualified anesthesiologists, who are trained and have been passed by the obstetric staff, are always available and supervise the administration of every anesthetic.

[9] Gladston, I.: Maternal Deaths—The Ways to Prevention, New York, Commonwealth Fund, 1937.

IMPROVEMENT OF PRENATAL CARE

Improvement of prenatal care should lead to reduced mortality in infants in the early age and low weight groups, while inadequate prenatal care tends to increase this mortality. Hence, it is the health officer's duty to cooperate with the physician in assuring that every pregnant woman has the advantage of continuous care of the best quality throughout pregnancy.

Toxemia is amenable to control through provision of adequate prenatal care, since, if the woman with toxemia is discovered early by her physician and he administers proper treatment, in many cases the disorder may be alleviated. It is also believed by many that, with proper diet and care during pregnancy, the development of toxemia may be prevented.

Lack of adequate, early, and continuous prenatal care leads to a high incidence of premature births, particularly among those of lower socioeconomic status. Lack of an adequate diet with all of the essential proteins, vitamins, and minerals, particularly iron, to prevent anemia, are believed by many to play a most important role in these cases. When prenatal care is completely adequate it decreases the chances of premature birth in many cases and helps avoid the complications of pregnancy, labor, and delivery, thus reducing the hazards to the newborn infant. Even the best possible hospital equipment and delivery care may not be able to counterbalance the ill-effects of faulty prenatal care.

Unhygienic conditions often prevail in the homes of those of lower socioeconomic status. Furthermore, the mothers from such homes may be shiftless in their attitude toward securing adequate prenatal care. It is the health officer's duty to attempt to overcome these effects of lower socioeconomic status by encouraging the personnel entrusted with the care of these women to more thoroughly and meticulously guide them through the critical periods of pregnancy, labor, and delivery. This can be accomplished more satisfactorily when all interested agencies, including physicians, nurses, and social agencies, cooperate with the health officer. The undoubted effect of low socioeconomic status in producing high mortality in newborn infants can, in part at least, be obviated by such proper corrective action in providing adequate prenatal care.

Such corrective action involves getting the pregnant woman to the physician early. This can be done, first by making pregnancy reportable by code number, the physician being the only one having the person's name and address, and secondly, by following up each known case of pregnancy just as we follow up all contacts to contagious diseases, all infants and young children who have not been given protective inoculations against diphtheria and whooping cough, and all contacts to venereal infection. This involves, as an emergency measure, assigning our health department forces, nurses, physicians, and all other available personnel, into areas of low socioeconomic status, and literally by a door-to-door campaign, making sure that every known pregnant woman is receiving the type of care she merits just as we used a successful case-finding, case-holding program in our campaign against venereal diseases. When the quality of prenatal care is optimal, deaths early in infancy will decline.

Such a program of assuring adequate prenatal care for all pregnant women can also be made a part of a community premature prevention program, because the first step in the prevention of prematurity is to make sure that the pregnant woman goes to the physician early and continuously and receives an adequate diet, including supplemental vitamins and minerals, as well as hormones, if indicated. It will give the physician a better chance to utilize every known available means at his command to help prevent premature birth.

Immediate skilful care is provided in all cases in the city-wide premature care program such as we established in 1935, based on the plan of Dr. Julius Hess. Such a program requires that every hospital have nurses especially trained to give instant, constant, and continuous care to the small premature infant, have all of the equipment necessary to provide proper care, and have established proper procedures to give adequate obstetric care to the mother. Skilful delivery of the premature infant may aid in reducing the hazard of intracranial hemorrhage, which is so often responsible for a fatal outcome and for crippling in those that live.

A capable attendant and necessary equipment in the delivery room when a premature birth is expected is a necessity if mortality among these infants is to be reduced materially. The attendant's activities must start instantaneously after delivery to clear the infant's airways, simultaneously keeping the infant warm and in an atmosphere with sufficient oxygen and humidity. Once respiration has been established the premature infant must be promptly and properly transported to the premature nursery, where care by skilful physicians and nurses is required.

SUMMARY AND CONCLUSIONS

Deaths on the natal day are the long-neglected field of infant mortality. As a result, in the last 40 years there has been practically no reduction in the death rate of the natal day period, so that now the deaths of this period make up more than one-third of all of the infant deaths. This condition presents an alarming situation, since many needless deaths continue to occur even though much new information is appearing in the medical literature concerning the reasons for and ways of preventing them. Furthermore, utilization of all previously available acceptable information would aid in materially reducing these deaths.

I have stressed the areas that have been neglected and, at times, may have appeared to belittle the physicians' efforts and those of the hospitals and health department; however, it is by no means my purpose to give the impression that the hospitals in Chicago do not come up to the standards of those in all other parts of the United States. I have not particularly called attention to many of the things that we did to attain the enviable position of having the lowest average infant mortality rate for the 10 year period from 1940 to 1949 of any of the 10 largest cities in the United States.

Nevertheless, there is still much to be accomplished in reducing needless infant deaths, but it requires action to make any appreciable further reduction in mortality. Most effort must be concentrated on the first three days of life and on infants of low weight who die mainly from abnormal pulmonary ventilation and injuries at birth. Deaths in these age, weight, and cause groups are, as yet, far from being under satisfactory control.

As a result of careful analyses of the causes of death and the factors contributing to them, we have inevitably arrived at the conclusion that concentration of effort is required, with complete cooperation of the patient, in improving prenatal care of women of low socioeconomic status and in constantly providing for skilful natal care of the mother-to-be in the hospital by obstetricians and optimal postnatal care of the infant by pediatricians. Our failures in the past have resulted because we have not constantly and consistently provided for this type of prenatal, natal, and postnatal care.

We have now set up a program that we believe will lead to the correction of the deficiencies of the maternity services in hospitals and will enable us to make sure that every pregnant woman receives adequate care from early in pregnancy until termination of delivery, and that the infant also will be given optimal care. More detailed and complete reports of the work of the Chicago Health Department in the control of early neonatal mortality are available in reprints which can be obtained from the author.

7410 Oglesby Ave.

ROLE OF THE PEDIATRICIAN IN PREVENTION OF NEEDLESS NEONATAL DEATHS

Stewart H. Clifford, M.D., Brookline, Mass.

The pediatrician responsible for the newborn in an obstetric hospital has three major obligations. First, he must apply all available knowledge to the protection and care of his charges so that they may survive the hazards of this dangerous period of life without future handicaps. Secondly, he must strive, with the help of all allied disciplines, to extend the boundaries of present knowledge to the end that fetal and neonatal morbidity and mortality can be reduced. Thirdly, he must disseminate this special knowledge through every available medium so that babies everywhere may benefit.

A revision of the American Academy of Pediatrics' manual "Standards and Recommendations for Hospital Care of Newborn Infants—Full Term and Premature" is about to be published [1] and should be made the bible of the newborn service. This manual contains standards that must be met by every hospital, irrespective of size or resources, attempting to care for newborn infants. A strict adherence to the spirit and letter of this manual by every nursery in the country would bring a reduction in needless neonatal deaths more surely than any other step that could be taken. It is obvious that the pediatrician in charge of a newborn service must assume the personal responsibility of making a critical survey of his local situation and insist that the medical service, nursing service, physical facilities, techniques of care, and record system fulfill at least the minimum requirements.

The Chicago study [2] demonstrates the need of a fresh approach to the problem of neonatal mortality. Prior to the study, Chicago's neonatal mortality had fallen from 36.1 in 1925 to 27.5 in 1935. From the start of the study in 1935 to 1940 neonatal mortality fell to 20.3 (a reduction of 26.2%), and from 1940 to 1950 the neonatal rate went to 19.4 deaths per 1,000 live births (a reduction of only 3.9%). A similar change was occurring in the United States as a whole; from 1935 the rate of 32.5 fell to an estimated 20.2 in 1951, a 37.8% reduction. The experience of many large obstetric hospitals proves that this general neonatal mortality of 19 to 20 per 1,000 live births does not represent an "irreducible minimum" but that existing knowledge and technique, if generally applied, could reduce this rate to 14 per 1,000 live births. With nearly 4 million births in the United States this would mean a salvage of 20,000 babies a year.

Prematurity, per se, is no longer acceptable as a cause of death. Premature infants die of the same conditions and causes that kill full term infants. It is true that premature infants are especially vulnerable; although they represent only 7 or 8% of all births, they contribute 60% of the total neonatal mortality. The distribution of the causes of neonatal deaths, as reported in the Chicago study, is quite representative of the experience encountered in other parts of the country: 47.5% postnatal asphyxia and atelectasis, 16.6% injury at birth, 15.8% congenital malformations, 13.4% infections, 5.3% blood dyscrasias, and 1.4% miscellaneous.

POSTNATAL ASPHYXIA AND ATELECTASIS

The pediatrician is seldom called on to take an active part in resuscitation of the newborn. This phase has usually been completed before the baby is turned over to the pediatrician for care. This does not prevent the pediatrician from having definite ideas as to the current errors being practiced in the resuscitation process. Those old enough to remember and young enough not to have forgotten will recall that in the pre-analgesia-anesthesia days of home delivery the need to resuscitate the product of a normal pregnancy and delivery was a rare occurrence. Most of these babies cried lustily as they crossed the perineum. The same type of patient, when transferred to a hospital for delivery and given analgesia and anesthesia, produced sleepy babies, 5 to 10% of whom were so slow in breathing and crying that resuscitation was deemed advisable. There is no argument that in either the pre-

Read in the Symposium on Prevention of Needless Neonatal Deaths before the Section on Pediatrics at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

[1] American Academy of Pediatrics: Standards and Recommendations for the Hospital Care of Newborn Infants—Full Term and Premature, to be published.

[2] Bundesen, H. N., and others: The Prevention of Needless Neonatal Deaths, reprinted from the annual report of the Chicago Health Department, Chicago, 1951.

analgesia or the postanalgesia era, some infants, the products of abnormal factors during pregnancy or labor, did, and do, require artificial resuscitation. In these infants the outcome has more to do with the preexisting damage at birth than with the type of resuscitation elected. The apprehension of the pediatrician concerns the "slow babies," who are given medication and who, if treated conservatively, will survive with no ill-effect, but who, if considered to be in much danger and only salvageable by heroic methods of resuscitation, may suffer more damage from the well-meaning manipulations of unskilled resuscitations than if left discretely alone.

In his efforts to do good the physician must not do harm. I am particularly alarmed at descriptions [3] that would lead any resident to assume he could pass a bronchoscope under direct laryngoscopy in a newborn, a procedure the most skillful laryngologists avoid unless there are very specific indications. Those with large experience in performing autopsies on the newborn have not encountered laryngeal or bronchial plugging that could possibly have been relieved by direct suction. One physician informed me that he would never use his laryngoscope unless the situation were desperate (with the infant in the third or flaccid stage of asphyxia) and then not to aspirate but to introduce oxygen directly into the trachea.

The emphasis and reliance on mechanical resuscitation gadgets, be they laryngoscopes, air locks, or rocking beds, in my opinion does more harm than good. In my experience positive pressure methods of resuscitation are frequently associated with the production of emphysema and pneumothorax. Emphasis should be concentrated on correcting, before and during delivery, the problems that may cause asphyxia at birth. The Boston Lying-in Hospital is as anxious as any to save more infants' lives, but very conservative methods of resuscitation have been used. In the past five years in 23,967 live births there have been 337 neonatal deaths, a rate of 14 per 1,000 live births. Our policy is to continue our present conservative methods until another procedure has demonstrated better results. Bloxsom's [4] neonatal mortality before using his air lock was 25 per 1,000 live births, and after a similar period during which he used the air lock his neonatal rate was 19 per 1,000 live births; compared to our own results it suggests that an approach to lowering the death rate might be better based on obstetric factors rather than on mechanical methods of resuscitation.

It may take several hours for the full-blown picture of severe respiratory distress to develop in the newborn infant. All infants should be watched closely, and at the first sign of possible respiratory trouble treatment should be instituted. There are certain situations wherein this syndrome is prone to develop in the newborn: after cesarean section, after a difficult delivery, in cases of intrauterine anoxia, and in cases in which the infants were delivered of diabetic mother or prematurely (here treatment should be instituted at birth). The air passages should be cleared of fluid by postural drainage and gentle suction. The stomach should be aspirated of its fluid content. The infant should be placed in an atmosphere of 40 to 50% oxygen. Although its value has not been proved, present practice is to provide high humidity through water fog or mist added to the atmosphere of the incubator, with or without a wetting agent. As infections are apt to develop in these infants, it is good practice to give prophylactic broad spectrum antibiotics or a combination of antibiotic therapy and chemotherapy that affects both gram-positive and gram-negative organisms.

Fortunately, although these infants are seriously ill, the vast majority recover completely on or about the fourth day. Since this condition is of such short duration during which time the babies are often comatose, the giving of food or fluid orally may be disastrous through further aspiration. The infants are frequently edematous and require no extra fluid; if, however, the clinical condition demands it, fluids can best be administered by hypodermoclysis.

A frequent and preventable cause of death in otherwise normal full term and premature infants is the regurgitation and aspiration of stomach contents. This accident occurs later in the neonatal period. A tragic outcome can be prevented only by constant observation and immediate treatment by postural drainage and suction. The aspiration episode may be considered serious enough to warrant prophylactic treatment to prevent secondary infection in the lung. The risk of aspiration is one reason the propping of formula bottles is frowned on and why rooming-in is usually delayed 24 to 48 hours, or until the mother has recovered from the effects of her delivery.

INJURY AT BIRTH

Intracranial hemorrhage, the result of birth trauma, has practically disappeared from modern obstetric hospitals. If more than a rare instance occurs it is an indication that methods of obstetric management should be made the subject of critical review. Spontaneous intraventricular hemorrhages still occur in premature infants, especially very immature ones. No methods are known at present to prevent this condition. The condition is characterized by the relatively late appearance of central nervous symptoms. The prognosis is bad. On rare occasions reduction of intracranial pressure and drainage of the old blood by lumbar and intraventricular punctures may produce a successful outcome.

Subarachnoid hemorrhages are usually the result of intrauterine anoxia. Advocates for and against treatment by repeated drainage by lumbar puncture will be found. It is our policy to perform frequent lumbar punctures and continue treatments until the fluid is normal. I think more infants recover and do so without hydrocephalus developing, than if expectant treatment is performed. Subdural hematomas are not infrequent in the newborn period, and it is very important in preventing later complications to make the diagnosis early. The symptoms may be convulsions, increased anterior fontanel pressure, lethargy, vomiting, failure to gain weight, and rapid increase in head size. The diagnosis is made by subdural punctures in conjunction with lumbar puncture. The treatment is repeated tapping and probably exploration and removal of part of the membrane. All suspected cases should have neurosurgical consultations.

CONGENITAL MALFORMATIONS

Infants with tracheoesophageal fistula are noted to pass excessive amounts of mucus from the moment of birth. This is enough on which to suspect the diagnosis, and by passing a catheter and finding that it ends in a blind esophageal pouch the diagnosis can be made. Early diagnosis and surgery have converted this once fatal anomaly into one with a good prognosis.

Obstruction of the second portion of the duodenum is intrinsic or secondary to malrotation of the cecum. The diagnosis is suspected when the newborn vomits persistently from birth. A flat x-ray plate of the abdomen without the need of a contrasting meal will show the large dilated stomach and first portion of the duodenum. Immediate surgery converts this once fatal condition into one with a good prognosis.

In slightly over one-half of the infants with prolonged obstructive jaundice[5] the cause is congenital atresia of the bile duct. In about one-quarter of the cases it is the result of inspissated bile secondary to erythroblastosis. In the remaining one-fourth it is the result of inspissated bile of unknown etiology and probably includes many cases of viral or infectious hepatitis. The establishing of an accurate diagnosis is very important in these patients, for in the inspissated bile group expectant and supportive medical treatment is accompanied by spontaneous recovery in all cases secondary to erythroblastosis and in 80% of the unknown etiology group. On the other hand, in congenital atresia of the bile ducts the defect could be corrected surgically in only 20% of the cases, and the operative mortality in the repaired cases was 80%.

It is imperative that those infants who have a condition from which they will recover spontaneously not be exposed to the possibility of operative death caused by surgical exploration. For this reason many physicians advise a two month waiting period in all infants with jaundice before surgical exploration is attempted. On the other hand, Gellis believes that true atresia can be disgnosed if a sufficient number of laboratory studies have proved that no bile is coming through the liver into the intestine. If no urobilinogen is appearing in the urine and if the bilirubin trend is generally upward. then surgical exploration should be carried out with no further delay.

INFECTIONS

It has been the general contention that the death of any infant from infection, after having survived the first week of life in good condition, must be considered a preventable death until proved otherwise. Epidemic diarrhea of the newborn is an example of one highly fatal condition that can be either prevented or controlled by the strict practice of approved nursery technique. The premature infants, owing to their natural susceptibility and to their prolonged hospital stay, are particularly prone to infection. This is especially true in nurseries where premature infants are admitted after being born outside. We have had an actual demonstration in the premature nursery of the Children's Hospital of how the needless loss of life from late infection can be brought under control. All of the premature infants cared for in this nursery were delivered outside our hospital and admitted for care and treatment. Between 1944 and 1947 there were 508 premature infants admitted, with a mortality of 50% (see table). Thirty-two per cent of the deaths took place after 1 week of age, and autopsy showed 85% of these deaths due to infection.

A program attempting to control this late infection problem was completed in late 1947. This plan included: (1) reconstruction of the nursery, isolating it and protecting it from contact with the rest of the hospital by as many barriers as possible, (2) terminal sterilization of all formulas and fluid for oral administration either by flowing steam or by steam under pressure, (3) a nursing and medical staff who dealt exclusively with the premature infants, (4) individual isolation of each infant from admission until ready for discharge, in an Isolette, and (5) prophylactic administration of 50,000 units of aqueous penicillin intramuscularly every six or eight hours and 20 to 30 mg. per kilogram of body weight of sodium sulfadiazine per 24 hours intramuscularly for 7 to 10 days. This procedure was carried out in all infants over 3 days of age and to all at any age whose history or examination caused one to even suspect contact with infection or possible injury or abnormality. The results of this program were dramatic and appeared at once. With 444 admissions between 1948 and 1952, the overall mortality fell to 34% and the per cent of those infants dying after 1 week of age fell from 32% to 8% (see table).

Mortality of Premature Infants in the Children's Hospital Nursery Before and After the Activation of a Program to Combat Infection

Age at Death (Days)	1944-1947 (%)	1948-1952 (%)
0- 7	68	92
8-21	13	4
22-35	12	1
36 +.	7	3
Total admissions	508	444
Mortality	50%	34%

There is an increasing concern about deaths from infection occurring in the first hours or days after birth. These infections must be acquired in utero or during the birth process. In some cases it is suspected that premature rupture of membranes, vaginal examinations stripping of the membranes, or operative manipulations may introduce the infection. In others maternal disease may be the cause; however, in many no likely etiological factor can be discovered.

Of the 58 premature infant deaths that took place at the Boston Lying-in Hospital during the 12 months of 1952 only one death took place after the first week of life. Six of the premature deaths occurring in the first seven days of life were due to infection (10%). Four of these infants had bronchopneumonia and died at the ages of 1¾ hours, 4 hours, 40 hours, and 43 hours, respectively. One died at 40 hours with omphalitis. One died at five days with purulent Escherichia coli meningitis and septicemia. Of the 22 full term infant deaths, 3 were due to infection. Two of these infants died at 3 days of age, one with E. coli bronchopneumonia, and the other with E. coli septicemia. The third died at 48 hours with early bronchopneumonia. It is clear that the pediatrician must obtain a very careful history of possible infection in the mother during late pregnancy and labor and be prepared to institute prophylactic therapy in appropriate circumstances.

BLOOD DYSCRASIAS

Hemorrhagic disease of the newborn was once a popular and common diagnosis, but it is now of rare occurrence. It is now realized that this is not a true disease but a syndrome that can be due to many causes. As these causes, such as erythroblastosis, sepsis, anoxia, and trauma, are recognized the bleeding is ascribed to its etiological cause and no longer referred to as hemorrhagic disease. A small residue of cases remain that appear to be caused by a true defect in the blood coagulation system such as congenital absence of fibrinogen. Such infants require careful study and supportive transfusions. The relation of vitamin K and abnormal prothrombin time to bleeding in the newborn is still not established. The rare bleeding referred to occurs with or without vitamin K having been administered to the mother and infant. There is need for a carefully controlled study to settle this relationship. Until such clarification is forthcoming, the point of wisdom would appear to be to continue administration of vitamin K to the mother before delivery and to the infant at birth.

Recent controlled studies [6] have proved the value of exchange transfusions in treating hemolytic disease of the newborn (erythroblastosis fetalis) as compared with single or multiple small transfusions. With exchange transfusions the mortality was 13%, whereas in matched cases treated by single transfusion it was 37%. These studies further demonstrated that the induction of labor three to five weeks before expected delivery in Rh-negative women resulted in a lower survival rate than when labor was allowed to proceed spontaneously.

Exchange transfusions have been shown to prevent the occurrence of kernicterus.[7] A microdetermination has been developed whereby bilirubin determinations can be performed on capillary blood. A correlation exists between the height of the bilirubin level and the occurrence of kernicterus. The bilirubin may act merely as an indicator of some other unknown substance responsible for the toxic damage to the brain. The bilirubin level rises very rapidly in the first few days of life in infants with hemolytic disease. Exchange transfusions, repeated if necessary, can lower the bilirubin level, and when this level has been kept below 20 mg. per 100 ml. kernicterus has not developed.

SUMMARY AND CONCLUSIONS

The present general neonatal mortality is between 19 and 20 per 1,000 live births. Many large obstetric hospitals in this country have demonstrated that existing knowledge and methods can lower this rate to at least 14 per 1,000 live births. The various causes of neonatal deaths are reported, and methods by which this loss can be prevented or minimized are discussed. In every instance in which methods to prevent needless loss of newborn infants are considered one immediately encounters the importance of the human factor. Reduction in neonatal mortality cannot be legislated; only through the enlightened cooperation of the many interested disciplines will real progress be made.

HOSPITALS AND PREVENTION OF NEONATAL MORTALITY

Charles U. Letourneau, M.D., Chicago

Survival of the newborn is a matter of national importance. The discrepancy between our birth rate and that of some other nations makes it so. It is imperative that we make every effort to compensate for our low birth rate by keeping infant mortality at a minimum. Studies conducted by public health workers, research undertaken by physicians, new concepts in nursing techniques, and improvement in the design, equipment, and personnel of hospitals have all helped to prevent neonatal mortality, but much remains to be done. It has been said [1] that improved hospital care alone can reduce the annual death rate among premature infants by 20,000. This is a challenge that must be and has been accepted by hospitals.

As community organizations, hospitals must bear a fair share of the task of prevention of neonatal deaths. Theoretically, hospitals provide the facilities to assist physicians and nurses in practicing their arts to the best advantage. Actually, hospitals are required to do much more than that. As educational institutions, they are active partners of the public health system in educating the people to better standards of health. They do this by participating actively in integrated public health programs. They cooperate closely with the medical, nursing, and paramedical professions in teaching and research. They also maintain their services at the highest peak of efficiency so that the quality of medical care rendered by physicians and nurses within their confines may also be of the best. With the medical profession, hospitals have voluntarily embarked on a program of self-accreditation [2] with the object of improving hospital care throughout the nation.

In the specific area of hospital care of the newborn, hospitals are working closely with the specialities of

[2] The Joint Commission on Accreditation of Hospitals Bulletin, vol. 1 (Nov) 1952.

obstetrics and pediatrics in an attempt to set minimum standards that will assure adequate care of the newborn and prevention of neonatal mortality. A measure designed to prevent prematurity, for example, is the scrutiny of the rate of cesarean sections in the hospitals. If the cesarean section rate exceeds 5% of the total births in the hospital, the medical staff of that hospital is urged to investigate its obstetric practices. In the areas of public health education, prenatal care, and obstetric and pediatric practice, hospitals can and do render much assistance to the medical and nursing professions.

The prime responsibility of the hospitals, however, begins with the birth of the infant and continues through the stay of the infant in the hospital until it is discharged. The not very profound observation has been made that the better the care in the hospital, the lower will be the mortality among newborn infants. The tremendous resources now available in the medical, nursing, public health, and hospital fields today make this statement axiomatic.

HOSPITAL PERSONNEL

The hospital contribution to the problem of prevention of neonatal mortality depends to a large extent on the trustees and the administrators of each hospital. Unless these persons are interested, the vast store of scientific knowledge concerning the newborn may be wasted or remain unused. Initially, the greatest attribute that a hospital administrator can possess is a strong desire to do something about the problem of neonatal mortality. Next to this, he must have the ability to stimulate others to want to do something about it too. As coordinator of the efforts of professional, technical, and paramedical staff in his hospital, he can be a powerful inspiration to them in achieving the desired goal. But his zeal must extend beyond the personnel of his own hospital and must reach the interest of the medical and nursing professions, the public health workers, and the people of his community. This is much to expect of a hospital administrator, but, if he has the "will to care," the task is half accomplished. Although he may not know very much about the problem in the beginning, the resourceful hospital administrator takes measures to obtain the knowledge, the facilities, and the equipment needed to achieve a good program of neonatal care.

As a first step, the hospital administrator must provide personnel, accommodation, and facilities to assist the medical staff of the hospital in giving proper care to the patients. He seeks to attract the best qualified physicians to his hospital and to his community, so that the hospital facilities can be used to best advantage. To meet this particular problem, he will invite competent obstetricians and pediatricians to practice in his hospital. There may be limitations, however, to his opportunity of obtaining the best men in the field. His hospital may not be large enough to support the most competent specialists, and his community may not be extensive enough to give them the scope their specialties demand.

Failure to secure certified specialists, however, need not dismay the enterprising hospital director. A hospital is only obliged to render the best service that it can with the staff and the facilities at hand. He will try to interest a good general practitioner in the problem of newborn care and encourage him to acquire more specialized knowledge on the subject. One enthusiastic general practitioner in a community can make a greater contribution toward improving the care of the newborn than a dozen uninterested specialists.

Although he may not be competent to pass judgment on the quality of medical practice in the hospital, the hospital administrator can still contribute to better care by calling attention to national standards established for the care of the newborn by such bodies as the American Academy of Pediatrics.[3] Administrative insistence on minimum standards in the hospital should not be resented by the medical staff or construed as lay interference in medical practice, for the hospital administrator has a duty to insist. Everyone is presumed to be interested in reducing mortality, and, if recommendations of national, public-spirited organizations are to be of any value at the local level, they must be put into effect.

NURSING CARE

Almost as important as the medical care is the quality of nursing care of newborn infants in the hospital. The nursing care of the newborn is now recognized as a specialized art that requires much knowledge and experience. As in the medical specialties, the highest quality of nursing care may be restricted by a lack of qualified personnel and for the same economic reasons. Once again, the "will to care" is the greatest single factor in good nursing care of the newborn. An interested general duty nurse should be found and stimulated to acquire more knowledge about neonatal care. If facilities for training nurses in the care of the newborn are available nearby, the resourceful hospital administrator will arrange to have interested members of his nursing staff instructed there. If adequate facilities for such training are not readily available, the hospital may set aside a sum of money provided by the trustees or by the women's auxiliary of the hospital for training nurses at a larger hospital in which acceptable procedures are in use. When the volunteer nurse has learned the techniques, she can teach others. In this way, a reasonably good nursing staff to care for the newborn can be assured, even to a small hospital of limited means.

LOCAL ASSISTANCE

The smart hospital administrator takes advantage of all local assistance facilities to secure better care for his patients. The care of the newborn is no exception to this principle. The health departments of the municipality, region, or state in which the hospital is located may have much to offer in the way of advice, personal consulting service, or even financing. The administrator will certainly enlist the help of the local medical and nursing societies, voluntary organizations, social agencies, and hospital associations to advance his purpose. In the United States, sources of available help are almost unlimited if hospitals will take the trouble to look for them.

Many government authorities have enacted special laws for the hospital care of the newborn. These laws are a welcome aid to raising the standards of medical and nursing practice in hospitals. In some cases, however, they do not go far enough; they are minimum only. Hospital administration has the duty to see that the laws are complied with, but no hospital should be satisfied with minimum standards. It should strive to give the best. Thus, regulations for the management of newborn nurseries should be enacted within each hospital, and, in preparing such regulations, the responsibility falls squarely on the medical and nursing personnel of the hospital. In this situation the hospital administrator provides the staff work for writing regulations but should insist at least on the minimum standards recommended by the national bodies even in the face of opposition or apathy.

---

[3] American Academy of Pediatrics: Standards and Recommendations for Hospital Care of Newborn Infants: 1953 Revision, to be published.

WHAT MUST BE PROVIDED

On the material side, the hospital administrator is responsibile for providing adequate accommodations for the newborn. This involves planning for square footage, air space, air conditioning, and other items of adequate design and construction. Equipment must be procured, such as incubators, resuscitation apparatus, oxygen, and similar items that are necessary to the proper care of the newborn. The administrator must maintain, as well as provide, in good working order the accommodations and equipment so that the tiny patients can obtain the maximum benefits from the facilities that have been provided.

In planning facilities and selecting equipment, the hospital administrator leans heavily on the medical staff. Nevertheless, he is not without resources, even in the absence of such advice, for the architectural and functional layout of the nursery has been standardized to some extent by the United States Public Health Service,[4] and the minimum requirements have been laid down. In the same way, the American Hospital Association conducts a continuous program of research on ways and means of improving service in the nursery. To give some examples, the association is presently inquiring into the efficiency of incubators and is following with keen interest the reports of research that is presently being conducted on the cause of retrolental fibroplasia. The solution to this problem might involve a completely new approach to the care of the premature infant in the nursery with consequent changes in design and modification of equipment presently in use. In the last analysis, however, it is the medical staff or the pediatric staff, if there is one, that has the main responsibility of giving proper advice as to whether the layout in the hospital is satisfactory or not.

ASPECTS OF CARE

The various procedures carried on in the nursery for the newborn are also a concern of the hospital administrator. The preparation of the formulas, for example, involves many administrative services. A special room must be set aside; techniques must be established and maintained; and the ingredients must be mixed and delivered to the small patients at the right time, at the right temperature, and by the right person. The drugs and the materials for the treatments prescribed must also be provided by the hospital and must be of the highest quality.

Having procured the personnel, the accommodations, the equipment, the supplies, and the administrative services, the responsibility of the hospital administrator is not nearly ended. By means of a system of reporting and recording, he must be in a position to evaluate the services rendered by his hospital and by the physicians who practice in it. Possibilities of improvement in the service must be quickly called to the attention of the medical and the nursing staff. It is standard practice, therefore, to alert the hospital administrator as soon as a case of diarrhea is discovered in the nursery. He must mobilize all his resources to isolate the patient and to prevent further spread to other patients. An epidemic of this disease is a black mark against the hospital. He may also have to do a lot of explaining to the health department.

The hospital administrator is as much concerned with the mortality and morbidity of the newborn in his hospital as are the physicians and nurses on his staff. A poor record is not only a reflection on the quality of medical and nursing practice in the hospital but also a reflection on the quality of his administration. From the standpoints of both public and personal interest, the hospital administrator must do everything in his power to reduce mortality in the newborn in his hospital.

FINANCE

Needless to say, a good program to prevent neonatal mortality involves finance. The care of the newborn, and especially that of the premature infant, is a costly undertaking. Ways and means must be found to finance the program, and this falls within the domain of the administrator. The burden of paying for this service should fall primarily on those who use them, namely, the parents of the young patient. Unfortunately, since most parents are in the low-income, younger-age group, they are seldom able to pay the full cost of maintaining such a program. Some insurance plans have been persuaded to underwrite the full cost of patient stay in the newborn nursery, but these are few. In some states and municipalities, funds are available to assist in maintaining a neonatal program. In some hospitals, the unpaid balance is distributed throughout other departments in the hospital by means of an accounting device. This sometimes involves raising room rent for adult patients or adding a little more to the charges for roentgenograms or laboratory procedures. Some hospitals feel that this practice is justifiable in the public interest. In other hospitals, the trustees have set aside special funds for the purpose of making up the deficit between what the patient can pay and the actual cost of maintenance. Such funds may come from endowments or public subscription.

It cannot be denied that the saving of a newborn baby is a worthy cause with a tremendous public appeal. This aspect of the problem is not overlooked by the competent hospital administrator. Having organized a woman's auxiliary in his hospital, he should experience little difficulty in financing a program of this kind. He "never underestimates the power of a woman," and a prompt and enthusiastic response usually attends any appeal to help save infant lives whether the request be for a new piece of equipment or funds to train nurses in the care of the newborn or merely to make up the deficit in the nursery service. The public relations resources of the hospital are easily available to promote a campaign to remodel or rebuild a nursery, and the judicious approach to the community has rarely failed to produce results for such a worthy cause.

---

[4] Elements of the General Hospitrl: Revised Edition, Hospitals 26: 109, (April) 1952.

SUMMARY AND CONCLUSIONS

The hospital administrator can do much to prevent or reduce neonatal mortality on his own initiative, but lacking the precise professional and technical knowledge, he requires the assistance and advice of his physicians and nurses without whom he can achieve a minimum success only. Separately, all the interested parties, physicians, specialists, nurses, public health workers, and hospitals, have achieved a marked degree of success in lowering mortality in the newborn. It is of relatively recent date that a common, cooperative approach to the problem has been undertaken by all these groups acting collectively and together. There seems to be no limit to what can be accomplished in this field if all will contribute their knowledge, experience, interest, enthusiasm, and "will to care" to the common enterprise.

CLINICAL NOTES

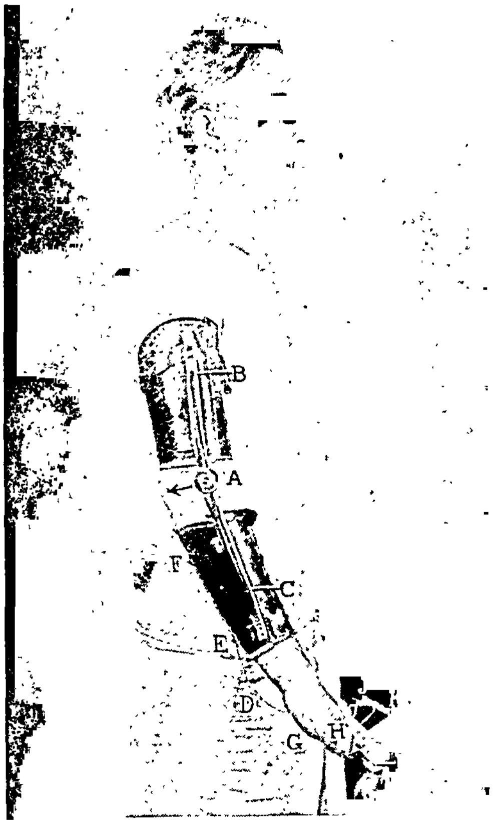
CORRECTIVE BRACE FOR THE UPPER EXTREMITY IN HEMIPLEGIA

Louis N. Rudin, M.D.
Daniel J. Cronin
and
John S. Croucher, Fort Howard (Baltimore), Md.

In the first few days after the occurrence of hemiplegia, the affected upper extremity is limp and appears flaccid, but actually, the muscles are spastic. After a variable short time a typical position is assumed. The upper extremity is adducted, the elbow flexed, the forearm pronated, and the wrist, fingers, and thumb flexed. If physical therapy and rehabilitation measures are not begun early, permanent contractures of muscles develop, and the upper extremity becomes fixed in the position described. There is a slow improvement in the brain tissue because of a partial resolution of the lesion. This results in improvement in the potential motor ability of the cortex. Unfortunately, this organic improvement of brain tissue cannot be translated into purposeful volitional movements, because the muscles and joints of the upper extremity have been fixed by contractures.

Many patients with hemiplegia of long duration have an increased potential ability to execute volitional movements of the paralyzed upper extremity, provided the muscles and joints are not fixed in a contracted state and allow for a range of motion. Heat and passive stretching, both manual and with pulleys, can be used to overcome these contractures. Since treatment is usually given only once daily in the average office or clinic, progress of the patient is extremely slow.

A special upper extremity brace has been developed to overcome the contractures as quickly as possible. The main feature of the brace is a series of springs that act at the elbow, wrist, fingers, and thumb in a direction opposite to that of the contractures. The constant tension produced by these springs gradually overcomes the contractures. The brace is taken off for physical therapy and is put back for its tension effects between treatments. It can be used for overcoming flexion contractures of the upper extremity from any cause.



A steel spring, *A*, is attached to the brace at posts *B* and *C*. The spring produces tension in the direction shown by the arrow, forcing extension of the elbow joint. The wrist is extended by a curved steel spring, *D*, attached to the bands of the forearm section of the brace at *E* and *F* and to the palmar pad, *G*, of the "reverse knuckle bender" (Bunnell, S.: Surgery of the Hand, ed. 2, Philadelphia, J. B. Lippincott Co., 1948, p. 137, fig. 96, Q). The "reverse knuckle bender," *H*, *I*, is tensed by rubber bands, *J*, *K*, producing extension at the metacarpophalangeal and interphalangeal joints. Rubber bands are attached to a thumb cuff and to a spring steel wire riveted to the radial side of the forearm cuffs, producing abduction of the thumb.

Pulley exercises are used to overcome the abduction contractures at the shoulder joint. A pulley is fixed to the ceiling or the upper part of a door jamb, and a loop is made in one end of the pulley rope to suspend the affected hand. The other end of the rope is passed through the pulley, and a series of knots for proper gripping is made at about three inch intervals. The patient grasps the rope with his unaffected hand and produces active assistive and passive motion in a seesaw manner to the involved upper extremity.

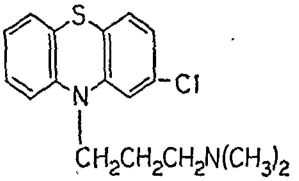
NEW ANTIEMETIC DRUG

PRELIMINARY REPORT

Dale G. Friend, M.D.
and
James F. Cummins, M.D., Boston

Nausea and vomiting constitute a symptom complex as distressing and almost as common as pain. It is surprising how little had been learned about the mechanism and control of nausea and vomiting until comparatively recent times. Everyone has experienced these symptoms at some time or other and has felt keenly the lack of really efficient measures for their relief. In the laboratories of Rhône-Poulenc, a chlorinated phenothiazine was synthesized, which has the following formula:



10-(γ-dimethylaminopropyl)-2-chlorophenothiazine hydrochloride.

This substance, which will be referred to as compound 2601-A, was soon shown by French investigators to have several unique properties,[1] among which is the ability to block the emetic effect of apomorphine in animals. This immediately suggested that it might be a highly useful antiemetic drug.

METHOD

After thorough studies in animals and a limited number of patients had shown the drug to be without observable toxic effects,[2] studies were initiated at the Peter Bent Brigham Hospital to determine its effectiveness against a variety of agents and conditions that cause nausea and vomiting in patients.

Compound 2601-A was first used cautiously in patients in the terminal stage of carcinoma and uremia, each condition being complicated by serious nausea and vomiting. A dose of 25 or 50 mg. was given intramuscularly initially and again at four hour intervals, for three or four days, if necessary, to control the symptoms. Usually the initial dose arrested the vomiting, and the remaining doses could be given orally. The usual dose for oral use was 25 mg. given three or four times a day. In some patients, a dose of 50 mg. given three or four times a day was employed, but results were so satisfactory with the 25 mg. dose that it was seldom necessary to use the higher one.

RESULTS

To date, 70 patients have been studied, with gratifying results. The table shows the effect of the drug on nausea and vomiting caused by a variety of conditions and drugs.

Without doubt, compound 2601-A has a powerful selective effect against nausea and vomiting and is effective whether given orally or intramuscularly. It acts in almost all patients without producing any degree of sedation or other evidence of action on the central nervous system. It is much more effective than diphenhydramine, tripelennamine, or dimenhydrinate as an antiemetic, since it promptly proved effective in patients in whom vomiting had not been relieved by these drugs.

Nausea and vomiting ceased usually within one hour after injection or oral administration of compound 2601-A. Often patients who had been unable to take anything by mouth for days were able to eat their next meal. In one patient with nausea and vomiting of three days' duration, secondary to toxic labyrinthitis, the vomiting immediately cleared, but the dizziness remained; the patient was, however, able to enjoy his meals. Another patient who had nausea, vomiting, and hiccuping of 10 days' duration, secondary to uremia, was relieved of gastrointestional symptoms, but the hiccups remained unabated.

Effect of Compound 2601-A on Nausea and Vomiting

Cause of Nausea and Vomiting	Result of Use of Compound 2601-A
Diseases	
Carcinomatosis	Controlled
Labyrinthitis	Controlled
Lymphomatosis	Controlled
Psychological vomiting	Decreased
Uremia	Controlled
Vomiting of pregnancy	Controlled
Drugs	
Disulfiram (Antabuse) plus alcohol	Prevented
Folic acid antagonist	Stopped promptly
Aureomycin	Stopped promptly
Codeine	Stopped promptly
Meperidine	Stopped promptly
Methadone	Stopped promptly
Morphine	Stopped promptly
Nitrogen mustard	Helped prevent
Oxytetracycline (Terramycin)	Stopped promptly
Protoveratrine	Stopped promptly
Urethane	Stopped promptly

A series of 35 patients who were under the influence of alcohol were given 1.5 gm. of disulfiram (Antabuse) and 150 to 175 mg. of compound 2601-A over 48 hours, a regimen suggested by the observations of Martensen-Larsen,[3] who found diphenhydramine (Benadryl), sodium chloride, and disulfiram an effective combination in the treatment of such patients. After the disulfiram-compound 2601-A treatment, no nausea or vomiting developed, and the patients rapidly recovered from their alcoholic state with a minimum of undesirable residual effects. Often, they promptly went to sleep and awakened sober and relaxed. They were able to return to their employment much more promptly than was possible after use of any of the other well-recognized methods of relieving alcoholism. In a few patients who had nausea and

vomiting from the disulfiram-alcohol reaction, compound 2601-A promptly suppressed the nausea and vomiting.

Nausea and vomiting due to medication with aureomycin, oxytetracycline (Terramycin), protoveratrine, or narcotic analgesics were also promptly controlled. Some patients receiving nitrogen mustard therapy were protected from the usually attendant nausea and vomiting if compound 2601-A was given. No change was made in the methods of administration of the nitrogen mustards; sedation was administered as usual, and the mustards were given in divided doses. If 75 mg. of compound 2601-A was given in three divided doses within a 12 hour period prior to intravenous administration of nitrogen mustards and for a similar period after such therapy, the nausea and vomiting was prevented or greatly ameliorated.

SIDE-EFFECTS

Dryness of the mouth and mild sedation developed in a few patients. In three, after a dose of 50 mg. of the drug had been given, transient faintness, flushing of the face, and palpitation developed. One of these patients was an 80-year-old, severely asthmatic patient, in whom, incidentally, the asthma cleared for several hours. Occasionally, a patient experienced some slight pain and tenderness at the site of intramuscular injection. Careful clinical and laboratory studies, including electrocardiograms, hematological surveys, and urinalyses, of patients who received compound 2601-A in a dose of 25 mg. three or four times a day for three months have shown no indication of untoward effects. The following case reports illustrate the use of this drug in various conditions.

REPORT OF CASES

CASE 1.—A 35-year-old woman entered Peter Bent Brigham Hospital with disseminated lupus erythematosus of 5 years duration and chronic renal insufficiency, an elevated blood urea nitrogen level (220 mg. per 100 cc.), and severe hypertension. Nausea and vomiting developed, possibly because of the severe uremia. The patient was given 50 mg. of compound 2601-A intramuscularly on Dec. 23, and 100 mg. in divided doses on Dec. 25, with complete clearing of the nausea and vomiting. The patient ate her meals for the first time in a week and felt much better after the use of the drug. No toxic side-effects were observed, despite the severe renal damage and damage to other organs brought about by the disease. As long as the patient has received the drug, nausea and vomiting have remained suppressed. If a placebo was substituted, they returned within about 48 hours. This patient has been maintained on 25 mg. three times a day for almost three months.

CASE 2.—In October, 1952, a 53-year-old man was found to have peritoneal lymphomatosis. At that time he was given radiation therapy and did well. In early December, more radiation therapy was required, and subsequent to this nausea and vomiting developed. At first they were controlled by the use of dimenhydrinate, but later this drug seemed to make them worse. The patient continued to vomit yellowish fluid three to five times a day and grew progressively weaker and more fatigued. On Dec. 27, compound 2601-A therapy was started with a dose of 25 mg. three times a day. On the first day, the patient received the drug at 10 a. m., 3 p. m. and 9 p. m. On Dec. 28, he was doing well. There was no nausea nor vomiting, and he tolerated a soft diet. Compound 2601-A was then given in doses of 25 mg. one hour before meals. On Jan. 1, the patient was tolerating food remarkably well; on that day, he was given 12.2 mg. of nitrogen mustard intravenously, and on Jan. 2 this dose was repeated. During this time compound 2601-A was being administered continually in a dose of 25 mg. three times a day. On Jan. 4, it was reported that the patient was eating better and had no pain; despite having received two courses of nitrogen mustard, he apparently was able to tolerate food well.

CASE 3.—A 72-year-old man entered the hospital with carcinoma of the prostate, chronic low abdominal pain, loss of weight, and fever of several weeks' duration. A previous trial of penicillin therapy had resulted in penicillin sensitivity, and, as a consequence, aureomycin was given in the hope that the fever could be brought under control. With a dose of 2 gm. a day of aureomycin, severe nausea and vomiting developed, which seriously incapacitated the patient. This continued despite withdrawal of the drug, and the patient was given compound 2601-A, 50 mg. intramuscularly and then 25 mg. orally four times a day for the next two days. Four hours after he received the intramuscular injection, all nausea and vomiting disappeared, and the patient fell asleep. It was noted that he appeared drowsy and tended to sleep more than normally. This was thought to be a result of relief from the severe nausea, vomiting, and retching that had been experienced for the previous 48 hours. The next morning the patient ate the most food he had taken in days, and he has since shown steady improvement in appetite.

CASE 4.—A 60-year-old white man, chronically alcoholic, who had been taking disulfiram for 19 months, stopped taking the drug and again began to drink. He had been on a drinking spree for about one week and had consumed large quantities of alcohol when he was given 1.5 gm. of disulfiram over a 24 hour period by his wife. When he was first seen a moderately severe disulfiram-alcohol reaction had developed. He was flushed and had tachycardia, with a heart rate of 130 beats per minute. He was not hypotensive but was nauseated and was vomiting vigorously. One hundred milligrams of compound 2601-A was given intramuscularly. The nausea and vomiting promptly stopped, and within 24 hours the patient could tolerate bland foods. He made quick and uneventful recovery from this reaction.

CASE 5.—A 34-year-old housewife entered the hospital because of severe anuria from lower nephron nephrosis. When she was 22 weeks pregnant, the placental membrane had ruptured spontaneously, and two days later she had delivered a macerated fetus. Vaginal crepitus was noted at that time. Within two days marked bronzing of the skin had developed. The hematocrit had dropped from 36 to 10% Hemoglobinuria and finally complete urinary shutdown had developed. Laboratory studies showed a blood urea nitrogen level of 200 mg. per 100 cc., a carbon dioxide combining power of 15 mm. per liter, and a serum chloride level of 114 mEq. per liter. Clostridium perfringens was cultured from a blood specimen. For six days prior to admission, the patient had had persistent and progressive nausea and vomiting. She was immediately given compound 2601-A intramuscularly, 50 mg. four times a day. After the initial injection, nausea and vomiting ceased. The next morning the patient's appetite returned, and she was willing to take food by mouth. Compound 2601-A therapy was stopped after 48 hours and she remained symptom-free for three days, when nausea and vomiting recurred. Again they were controlled with use of the compound.

SUMMARY

A new drug, 10-(γ-dimethylaminopropyl)-2-chlorophenothiazine hydrochloride (compound 2601-A) was shown to be effective in suppressing nausea and vomiting caused by a wide variety of clinical conditions, e. g., carcinomatosis, labyrinthitis, lymphomatosis, and uremia. It was also found effective in preventing or controlling the nausea and vomiting caused by disulfiram (Antabuse) administration to patients under the influence of alcohol and that produced by aureomycin, folic acid antagonist, codeine, meperidine, methadone, morphine, nitrogen mustard, protoveratrine, oxytetracycline (Terramycin), and urethane therapy. The only side-effects observed were dryness of the mouth, occasionally mild sedation, and rarely a mild transient attack of faintness, palpitation, and flushing of the face.

MEDICINE, WARFARE, AND HISTORY

John F. Fulton, M.D., New Haven, Conn.

It is not commonly realized that many of the most significant advances in medical science have been made by medical officers in the armed services or by civilian physicians working under the stimulus of wartime exigency. Whereas the ultimate compensations of war to any society are usually few and seldom recognized, in the field of medicine, over the years, they have been numerous and many of them highly important. A number of examples may be cited from the historical record.

In his illuminating series of notes on the history of military medicine, the late Col. Fielding H. Garrison[1] made the observation that, while there were military surgeons in ancient times who occupied positions of responsibility and respect in the armies of Greece and Rome, it was the Swiss Confederation, in the 14th century, that antedated all other nations of modern Europe in state care of the wounded. Municipal ordinances were issued notifying the individual soldier that his government was behind him and would look after his welfare on the field of battle. The eminent historian Conrad Brunner[2] points out further that, from the time of the battle of Laupen in 1339, the Swiss archives are replete with records of monies distributed for the care of the wounded and their dependents. Brunner also discovered that barber-surgeons were engaged by individual Cantons to attend the wounded after battle. The Swiss thus set an example to all of the other warring countries of western Europe.

In France in the 1470's we find that Charles the Bold, Duke of Burgundy, had placed a surgeon in each company of 100 lancers, that is, one surgeon to 800 men. It is also recorded that the lancers received £ 12 monthly from the Duke's coffers while his surgeon-physicians received only £ 5. When Edward IV of England joined Charles the Bold in the campaign against Louis XI, he brought with him a chief physician, two "body physicians," a surgeon, and 13 assistant barber-surgeons. These men, who attended the sick and wounded, gained valuable experience for dealing with civilian problems, injury, and disease when the wars had ended.

A century later we find Andreas Vesalius, founder of modern anatomy, serving as a military surgeon in the armies of Charles V. His contemporary, Ambroise Paré, who lived through the reigns of seven French monarchs and served four of them, not only introduced the ligature for arresting hemorrhage resulting from injury or amputation but also used antiseptic salves for dressing wounds. A man of high character, Paré spoke with authority and did more to place surgery on a modern basis, as Vesalius had anatomy, than any other person until the time of Joseph Lister. Paré was also a pioneer in advancing the art of rehabilitation of the injured. He devised many forms of prosthesis, including wooden arms, legs, mechanical fingers, false noses, and ears—advances that again were adopted by civilian surgeons.

During the 17th and first half of the 18th century, advancement of military medicine proceeded slowly, and there was no one comparable to Paré until the last half of the 18th century, when James Lind, the great British naval surgeon, appeared on the scene. There was, however, one notable figure in the 17th century, Richard Wiseman, who served the royalist armies in England throughout the civil war and after the Restoration and who was responsible for many improvements in surgical technique, including the art of amputation, especially in the case of gunshot wounds affecting the joints. His book, "Severall Chirurgicall Treatises," published in 1676,[3] is one of the important landmarks in the history of surgery, both military and civilian.

To James Lind, M.D. (1716-1794) (to be distinguished from James Lind, M.D. [1736-1812], also a Scotsman) of Edinburgh, a surgeon long in the service of the Royal Navy, we owe the first clear-cut proof that scurvy can be prevented by the use of citrus fruits among sailors on long ocean voyages. His "Treatise on the Scurvy," published in 1753,[4] is a classic, and as a result of it a dread disease, common not only among seamen but in civilian populations where citrus fruits are not readily available, has been virtually eradicated. Fully conscious of the importance of his discovery, Lind wrote in the preface to the first edition: "The subject of the following sheets is of great importance to this nation; the most powerful in her fleets, and the most flourishing in her commerce, of any in the world. Armies have been supposed to lose more of their men by sickness, than by the sword. But this observation has been much more verified in our fleets and squadrons; where the scurvy alone, during the last war [ending in 1748], proved a more destructive enemy, and cut off more valuable lives, than the united efforts of the French and Spanish arms."

WILLIAM BEAUMONT AND SILAS WEIR MITCHELL

In 1853 the American medical profession mourned the death of William Beaumont, U. S. Army surgeon, who, in addition to advancing the art of surgery in our armed forces, made a brilliant study of the processes involved in human digestion. When Beaumont was stationed at an isolated army barracks in northern Michigan, a French-Canadian courier, Alexis St. Martin, was accidentally shot through the stomach. Beaumont attended his wound with infinite care. When it healed it left a fistula that Beaumont looked on not as a mere wound but as a unique opportunity to inspect his patient's stomach mucosa by direct vision and to study the rate of digestion of individual foodstuffs through action of the gastric juices. He was also able to remove these digestive secretions and to study their action on food outside the body, a study that resulted in his celebrated monograph, "Ex-

periments and Observations on the Gastric Juice, and the Physiology of Digestion,"[5] which so well exemplified Pasteur's famous dictum, "In the field of observation, chance favours only the mind which is prepared."

The United States armed forces have had many other illustrious medical officers who have done original work through opportunity to study wounded men, ours as well as those of the enemy. Many names come to mind, such as that of John Shaw Billings; but no one during the Civil War occupies the position of Silas Weir Mitchell, a physiologist by training and a neurologist through special interest. Mitchell, with W. W. Keen (who ultimately became a celebrated Philadelphia surgeon) and G. R. Morehouse, early in the Civil War (1861) had occasion to study peripheral nerve injuries and the sensory and motor disturbances that result therefrom. Perusal of the protocols of their preliminary Circular Letter issued through the Office of the Surgeon General on March 10, 1864,[6] and of the monograph that they published later in the same year,[7] makes it clear that Mitchell was the dynamic force behind the study. His analysis of the problem illustrates his powers of observation and his genius for making sound physiological deductions. Among other things, Mitchell and his colleagues discovered that in certain cases following severance of an important nerve, especially when the nerve's disruption was associated with infection, there were abnormal sensory manifestations, i. e., hyperesthesia in the extremity affected, a syndrome that Mitchell named causalgia. The problem of causalgia has been studied for nearly a hundred years in both civilian and wartime cases of nerve injury, and it came to be most actively studied during World War II, when its incidence was frequent.

In retrospect, an even more important contribution of Mitchell and his collaborators lies in the clear-cut description of "primary" and "secondary" shock. Thus, in discussing the various types of shock, one reads in the circular on reflex paralysis:[6] "The majority of physicians will no doubt be disposed to attribute the chief share in the phenomena of shock . . . to the indirect influence exerted upon and through the heart. There are, however, certain facts, which duly considered, will, we think, lead us to suppose that in many cases the phenomena in question may be due to a temporary paralysis of the whole range of nerve centres, and that among these phenomena the cardiac feebleness may play a large part, and be itself induced by the state of the regulating nerve centres of the great circulatory organs. . . . But there do exist certain cases, more rare it is true, in which singular affections of the nerve centres, other than those of the heart, occurs as a consequence of wounds."

WORLD WAR I

During World War I there were many medical advances stimulated by the war itself, particularly in the sphere of prevention of infectious disease. It is said that when the Austrians attempted to invade the Balkans the front was held not by guns but by the louse and the devastating epidemics of typhus caused by the jumping creatures. It is estimated that nearly a million Austrian soldiers poised on the Balkan border perished from epidemic typhus. The Russian armies had much the same difficulty and so did those of other countries of western Europe. Our soldiers were similarly troubled in the trenches on the western front, but through use of hygienic methods there was far less devastation.

On the basis of the experience of World War I, every effort was made in World War II to protect our troops from typhus, especially in the Mediterranean theater. Meanwhile, DDT, the most effective insecticide then known, had been introduced and was used by the Eighth Army under the direction of General Fox and General Hume to delouse the population of Naples and other points of southern Italy. This practically abolished the typhus hazard among our occupation forces and the Italian civilians.

It would be difficult to enumerate all the special branches of medicine that have benefited by war research, but there is nothing so striking as the protection afforded our troops by mass inoculation, particularly against tetanus. To quote Brig. Gen. Elliott C. Cutler, chief consultant in surgery of the European theater of operations in World War II: "I would like to speak of the miracle which has occurred in eliminating tetanus from military surgery. Let me recall some figures for you. In our Civil War, the mortality rate was from 89 to 95 per cent. Shortly before World War I, under the benefit of antitoxin which was discovered and elaborated upon by the use of animals, the mortality rate had dropped to between 40 and 80 per cent. During World War I, large statistical evidence showed a mortality rate of 20 to 58 per cent; but, in this second World War, there were only 11 cases known to have occurred amongst 10,700,000 men. Of these 11 cases, 5 had been given toxoid and 6 had not. Moreover, in these 11 cases, there are records of only four deaths, two of which occurred in individuals who had received the basic series of toxoid but no booster dose, and two in individuals who had not received even the basic series. This is, in my mind, one of the great miracles of modern medicine. The basis of the establishment of a proper toxoid rests squarely upon animal investigation, and no greater debt could be acknowledged to our friends in the animal kingdom than this advance for the good of humanity."[8]

In World War I many other lessons were learned, particularly the importance of moving casualties rapidly from the front lines, before infection had set in. The mortality incidence from battle casualties was far less than in the Civil War or the Spanish-American War, but it was still high as compared with the mortality rate from casualties in World War II.

Harvey Cushing took the lead in dealing with head wounds, and, while he worked slowly, much to the consternation of other Allied surgeons, he took the rugged view that one wound well handled served a better purpose than a dozen hastily repaired wounds, since in nearly all

the latter cases the patients would die anyway. His paper published in the *British Journal of Surgery* in 1918 [9] is still a classic of wartime cranial surgery and has been widely quoted by Hugh Cairns, Eldridge Campbell, and others who dealt with battle casualties in World War II.

WORLD WAR II

Introduction of Antibiotics.—Between World War I and World War II there were many important contributions useful not only in time of war but for medical and civilian defense. Undoubtedly the most important were the developments in the field of the antibiotics. Much research had been done on them before 1939, but their introduction as therapeutic agents was greatly expedited by World War II. Sir Howard Florey and his resourceful team at Oxford were responsible for establishing the therapeutic potentialities of penicillin. They were the first to isolate it in pure form; they were also responsible for determining its effective dosage and for securing its large-scale commercial production. Several years ago when someone referred to penicillin as an outcome of wartime research Sir Howard protested, and his objections were well taken, for he had begun to work on the antibiotics in the early thirties; but it would have been many years before penicillin could have been made available in large quantities had it not been for the stimulus of war. The story of penicillin has been frequently told and need not be repeated here, particularly since Sir Howard and Lady Florey have recently published detailed monographs [10] in which the meaningful story of the antibiotics has been traced in detail.

Surgery has probably been more benefited by wartime research than any other branch of medicine. In World War I no surgeon would have dreamed of closing an infected wound, or even one that was potentially infected, without leaving a drain. Now, thanks to the use of chemotherapeutic agents such as the sulfonamides and penicillin, it is possible to close wounds of almost every description, even those of the abdomen, without drainage and without fear of subsequent complication from infection, provided all dead tissue has been carefully removed prior to the closure. So great at one time did confidence become in the effectiveness of the new chemotherapeutic agents that some of the younger surgeons grew careless and began closing badly contused wounds without "débridement," i. e., without careful removal of seriously damaged tissue. Such injured areas may be without circulation, and they therefore become the foci of serious infection, since the bloodstream is unable to carry antibacterial agents into such regions. Penicillin thus cannot be regarded as a substitute for good surgery but merely a highly important adjunct. These newer principles of traumatic surgery, as worked out in the war theaters, have had immediate application in all forms of civilian traumatic surgery, and they are rapidly being adopted in our surgical clinics, largely through the influence of the younger medical officers returning from active service.

A second important result of the use of penicillin and the sulfonamides has been the avoidance of unnecessary amputations and unnecessary removal of potentially viable tissue. With the greater confidence that these drugs are bringing to the surgeon he is able to operate much less radically. Formerly it was taught that all contused tissue should be removed from an injured area, but a contused muscle may still have an active circulation and therefore be capable of regaining its normal function. When the thigh muscle or the calf has been injured by a high-velocity missile, the muscle is generally contused over a large area and a surgeon of the old school would in most such instances amputate rather than risk secondary infection. During the last two years of World War II and during the Korean campaign countless extremities injured in this manner have been saved by combining penicillin therapy with conservative surgery. One of the burning arguments, however, that one still encounters in surgical amphitheaters turns on the criterion of tissue viability: how can a surgeon be certain that a contused muscle will recover its function? The old adage ran, "When in doubt, remove it"; a newer epigram might be, "If it bleeds, it can recover," and "When in doubt, leave it."

BLOOD FRACTIONATION

Surgery has also been influenced by wartime studies on human blood and the blood plasma fractions that have become available in pure form, again as a direct result of wartime medical research. At the beginning of the war, much effort was devoted to the preparation of blood fractions suitable for transfusion. Blood plasma (whole blood minus the red blood cells) was made available, but since many untoward reactions occurred from the transfusion of incompatible plasmas, and since under war conditions blood typing was often difficult or impossible, the plasma proteins were fractionated and the globulin fraction that carries the allergic potentialities of the blood was eliminated, leaving the albumins and fibrinogen. Albumin was then prepared in pure form and was thus made available for immediate transfusion without fear of complications.

It soon became obvious, and this should have been clear from our experience in World War I, that when men have sustained severe hemorrhage whole blood is needed for transfusion, not merely plasma or albumin, since many weeks are required for the body to regenerate its red blood cells. The British had attempted to collect and store whole blood in 1939, but their efforts were largely unsuccessful because of difficulties in preservation. In 1943 an effective preservative was developed by the U. S. National Research Council, and within a few months whole blood was being flown in enormous quantities to Europe as well as to all the outposts of our Pacific theater, as it is now being flown to Korea. So effective is this service that blood drawn on the west coast was delivered in refrigerated containers less than 48 hours later at points such as Leyte, and at the end of the war it was quickly reaching Seoul and other points in the Korean theater.

As a result of these investigations on blood and its fractions, the civilian surgeon has an imposing array of blood substitutes ready for his use at any time, and he is able to count on a supply of stored whole blood rather than having to find a blood donor at the scene of an accident or at some outpost of civilization. He has also come to depend on two other significant blood fractions, namely, fibrin and thrombin, which, thanks to the work of Edwin Cohn, Franc Ingraham, and others, are available in pure form and in combination can be used to stop the most stubborn hemorrhage, e. g., bleeding from the brain substance or the liver, which is notoriously difficult to arrest. A more homely use of the fibrin-thrombin combination is for stopping a nosebleed or the hemorrhage that so often follows tooth extraction.

Cumberlege, Oxford University Press, 2 v., 1949, and Florey, M. E.: The Clinical Application of Antibiotics: Penicillin, London, Oxford University Press, 1952.

Important new branches of medicine, important to the armed forces and to civilians alike, have been created by wartime necessity. Although no word has yet been coined to cover the great new area of chemical applications in disease control, i. e., insect repellents, insecticides, and antimalarials, which are now numerous because of our attempts to make military operations possible in tropical regions, this special field presents itself as a new and discrete branch of medicine and should be so recognized. Just as Major Walter Reed and Gen. William C. Gorgas made possible the building of the Panama Canal through control of yellow fever, so the repellents (against insect and shark) and the new insecticides made possible operations in the South Pacific in World War II that otherwise would have been too costly to contemplate. Other new and significant branches that have developed are aviation and submarine medicine.

AVIATION MEDICINE

Oxygen Administration.—Progress in aviation, stimulated by developments in military aircraft, has led to many advances of outstanding value both for medical defense and for civilian aviation.[11] One of these is oxygen administration. During the First World War, few fighter planes could achieve altitudes greater than 18,000 ft., and the use of oxygen, except in unusual instances, was not deemed a prime military necessity; hence, such oxygen masks as there were were crude in design and wasteful from the point of view of oxygen supply. The need for oxygen masks was well known, however, from early balloon ascent, and particularly from the tragic Tissandier disaster, which occurred on April 15, 1875. Three men had ascended in a balloon to an altitude of 28,000 ft., and all three were overcome by altitude sickness before they could breathe the oxygen that they had on board. As a result, two of the balloonists, Crocé-Spinelli and Sivel, succumbed, and Tissandier alone of the three survived. The intrepid French experimenter, Paul Bert, established the fact in a home-made pressure chamber that it was not low pressure as such that had caused the death of the two balloonists but rather the low pressure of oxygen at 28,000 ft. Paul Bert exposed himself, along with a bird and a rat, to a pressure of 430 mm. Hg. The bird vomited and appeared quite sick, and at a slightly higher altitude the bird was close to death and the rat uneasy. At that point, Professor Bert became dizzy and his pulse had increased from 60 to 86. He then began to breathe oxygen, his dizziness disappeared, and his pulse within two minutes had dropped to 64, but it was still impossible for him to whistle. He continued his ascent to an altitude equivalent of 29,000 ft. (428 mm. Hg), at which time the bird was prostrate and a burning candle had turned very blue, with its flame almost extinguished.

This celebrated experiment made it quite clear that oxygen must be available if planes without pressure cabins were to ascend to altitudes above 18,000 ft. Further study carried out during World War II made it clear that vision, mental alertness, and the capacity to fly a plane with safety began to diminish at altitudes as low as 5,000 ft., this being particularly true of night vision. Hence, when military aircraft began to ascend to altitudes of 25,000 and 30,000 ft. and later to 40,000 and 50,000 ft.[12] the problem of oxygen supply became acute and all the problems worked out for military aircraft were immediately applicable to commercial planes carrying civilians. It has been said that the Battle of Britain was won with a few oxygen masks. In a literal sense this is perhaps true, because Hitler's military pilots, both fighters and bombers, began in the summer of 1940 to come in at altitude ceilings well above the tolerance of an ordinary flier and they had developed systems of oxygen supply that for a brief time were superior to those of British fighters. Thanks to the efforts of the Flying Personnel Research Committee and particularly to one of its members, Sir Brian Matthews, the British developed a successful oxygen mask and a system of supply that made it possible for British fighters to meet German raiders at their own altitude, and through this circumstance the Battle of Britain was won, virtually in a single day, September 15, 1940, when 186 German planes were shot down. The *Luftwaffe* quickly decided it could no longer stand this rate of attrition. The British were tireless in their efforts to improve their oxygen masks and modes of supply, and our own air forces profited immeasurably by British experience, which was made freely available to the U. S. Army and Navy Air Forces.

Pressure Cabin Aircraft.[13]—It early became obvious to some investigators, including Paul Bert, that, if the gondola of a high-altitude balloon were artificially pressurized, a balloon might ascend higher into the atmosphere without endangering life. But years passed, and it was not until 1933 that the National Geographic–U. S. Army stratosphere flight was able to make an ascent in a pressurized gondola with adequate pressure control. In this memorable ascent, Auguste Piccard achieved an altitude of 72,395 ft., the highest altitude yet attained by man.

The experience encouraged the U. S. Army Air Corps to think of pressurized combat aircraft, and to Harry G. Armstrong, now Surgeon General of the U. S. Army Air Forces, must be given credit for having, through a historic Air Corps technical report, outlined the physiological requirements of sealed high-altitude aircraft compartments. This was a starting point for developments of pressurized planes in this country, the first of which (the

T.: A Bibliography of Visual Literature, 1939-1944, Washington, D. C., 1945.

[12] In the *Illustrated London News* for May 16, 1953, it is reported that on May 4 a new English turbo-jet bomber (Canberra type) reached an authenticated altitude of 63,668 ft., which stands as the altitude record for heavier-than-air machines under human control.

[13] The material in this and the following section is based on: Fulton, J. F.: *Aviation Medicine in Its Preventive Aspects:* An Historical Survey (Heath Clark Lectures, 1947), London, Oxford University Press, 1948. National Research Council: Decompression *Sickness,* Caisson *Sickness,* Diver's and Flier's Bends, and Related Syndromes, Philadelphia, W. B. Saunders Company, 1951.

XC-35) was flown in April, 1937. In this development the United States was ahead of both Britain and Germany, and thanks to the enterprise of the Lockheed Aircraft Corporation finally succeeded in making their stratoliners (B-307) and Constellations effectively pressurized. After 1946 Constellations began to make regular transatlantic flights at altitudes ranging from 18,000 to 24,000 ft., while the pressure in the cabins was maintained at an average corresponding to 8,000 ft.

Technical difficulties in pressure cabin aircraft prove numerous, and for the most part they stem from man's physiological requirements, i. e., maintaining cabin pressure, and, of almost equal importance, adequate ventilation. The average air passenger, without lung or heart disease and under the age of 70, is quite comfortable at an altitude of 8,000 ft., even though at that height his night vision may be somewhat impaired. But ventilation of the fuselage presents a very real problem because of the accumulation of water vapor and carbon dioxide; also in hot weather body odors and fumes from aircraft instruments and engines demand rapid change of air at appropriate pressure. In a completely sealed cabin a change of air of 2 to 3 cubic feet per minute per person will keep the humidity and the carbon dioxide at a tolerable level, provided there are no exhaust fumes.[14] Leaks in the pressure cabin equipment are inevitable, however, and with further experience it became evident that a change of at least 12 cubic feet per minute per person would be essential for comfortable air travel. This involved installation of larger turbo-pressurizers and air coolers to make the pressurized air tolerable from a thermal standpoint. Through experience gained during World War II these difficulties have now been largely overcome, and essential equipment has now been installed in all long-range, high-flying, pressurized passenger aircraft.

Explosive Decompression.—An ever-present hazard in pressurized aircraft, both military and commercial, is that of sudden or explosive decompression. Pressurized aircraft, such as the Constellation, is stressed to withstand a pressure differential of 6.5 lb. per square inch. This would permit flight at 30,000 ft. with an internal pressure equivalent of 8,000 ft. If a large military aircraft, flying at 30,000 ft., were suddenly depressurized by enemy action, the pilot, if he had oxygen available, could carry on, but other crew and passengers without oxygen would retain useful consciousness for about two minutes. If no oxygen were available, crew and passengers would become unconscious within a matter of minutes and death might ensue within a period of 8 to 10 minutes. Hence, commercial planes, in which explosive decompression might occur as a result of the breaking of a window, failure of turbos, or explosion of an observation dome, are not permitted to fly above 22,000 to 24,000 ft., since a large plane cannot descend rapidly enough to insure consciousness of the occupants, especially of the crew.

With military planes, which ascend to much greater altitudes, the situation is even more critical. For example, if pressurized military aircraft were flying at 52,000 ft. and were suddenly decompressed, the pilot would have only 15 to 20 seconds to get himself out of the plane, and, if he did not descend within three to five minutes through free fall to 20,000 ft., his heart would have stopped. A direct pressure dive might enable the pilot to achieve 15,000-20,000 ft., but he would be unconscious when he reached that level. In view of this circumstance it has been deemed safer to bail out for a free fall with a parachute that will automatically open at 10,000 to 12,000 ft. With rockets and the much-talked-of space ship, which will fly through ether in which there is no pressure and no oxygen, the paramount importance of maintaining adequate pressure levels is obvious, and the energy required to maintain pressure, let alone jet propulsion, is so great that even the most optimistic are loath to predict that the problem of fuel supply could be solved, despite all the resources of human ingenuity, within the life-span of this generation. Perhaps one might reach the moon, but how would energy be secured to insure return? More difficult conundrums have been solved in the past, but, although I happen to be an optimist with faith in the resourcefulness of some future generation, I believe that the only possible solution lies in atomic energy with all its weighty paraphernalia. "And so it turns out that in man's quest for mastery of the air a great step forward has been taken in the successful development of pressurized cabins. These developments, however, are in their early infancy from the engineering standpoint, and their use in larger transport planes, in rockets and jet-propelled craft, will succeed only if the limitations of the human frame, both in its structure and in its functions, are kept constantly in mind. And let us not forget that it was a flight surgeon and not an engineer who wrote the specifications for the first pressurized plane." [15]

Acceleration in High-Speed Aircraft.—The successful use of oxygen presupposes a steady blood circulation without undue gravitational pressure on the heart; however, it became obvious to the French flight surgeons in 1918 that rapid turns and dive pull-outs tended to diminish the flow of blood to the brain. In the Snyder Trophy Races in 1929, confusion and dimming of vision were encountered when the pilots were rounding the pylon; and in 1932 a man of great insight, Heinrich von Diringshofen of the German Air Ministry Research Laboratories at Tempelhof in Berlin, constructed a human centrifuge to simulate problems of acceleration in flight. Before this, however, two equally thoughtful Dutch investigators, Jongbloed and Noøyons of Utrecht, had studied the effects of acceleration on the level of the systolic blood pressure in animals. As a plane's speed is augmented or diminished, the pilot is pushed backward or forward in his seat by a force directly proportional to the rate of acceleration or deceleration. If the increase of speed occurs at 32.2 ft. per second, the pilot would be pushed against the back of his seat by a force equal to that of gravity, but, when pilots pull out of dive bomb maneuvers, the direction of the acceleration is from head to foot, and, as far as the circulation is concerned, there is a tendency to pull blood from the head.

Need for protection from high acceleration in aircraft has become even more acute in the last few years owing to the development of the fast-flying jet plane and the possibility of using rockets for human transportation. Even when planes were unable to fly at rates of more than 200 to 300 miles per hour, acceleration had become a vital problem, especially in dive bombers, and in fighter aircraft that were able to make fast turns. Now that jets are achieving speeds of 500 to 700 miles per hour, the need for protection from acceleration is vastly increased. The pneumatic pressure suit developed by Capt. John Poppen, USN (MC), Prof. F. A. S. Cotton in Australia, and Dr. Harold Lamport in New Haven, Conn., and many others, has served to give measurable and strategically significant protection for military pilots. Such suits have proved of inestimable value, especially during the D-Day operations, and more recently for our fighter pilots in Korea.

[15] Fulton,[13] p. 114.

Design for Safety—During the war there were many instances in which a fast-flying bombing plane crashed into a mountain side and everyone on the plane, except for the tail gunner, was instantly killed. Accidents such as this have stirred inquiry into the reasons for these apparently miraculous survivals. They lie in the fact that the rear gunner's head and the rest of his body were supported by solid structure at the time of the impact and in the fact that he was riding backward. Those situated in a more forward position in a crashing airplane are thrown from their seats because of insufficient strength of seat belts and seat moorings, and according to the wartime report of Whittingham, director general of medical services of the R. A. F. (and now of B. O. A. C.), 95% of the deaths in air crashes result from head injury, i. e., the head of the passenger is thrown violently against solid structure.

It became obvious, in view of episodes such as these, that rear-facing, heavily moored seats would confer a degree of passenger safety at least 10 times as great as that which could be achieved with forward-facing seats with fragile seat belts to hold the passenger in place in the event of accident. The British public and airplane manufacturers have already seen the virtue of rear-facing seats, and many of their new passenger planes are so equipped. In the United States the resistance on the part of both the flying public, and more particularly the aircraft designers, has been so great that to date only Northwest Airlines have seen fit to install rear-facing seats in commercial craft.

The principles involved in the greater safety from rear-facing seats are simple. If one falls to the ground and strikes one's head on soft earth, the head is decelerated in a matter of a few tenths to one half a second; the blow being thus softened, the accident victim may not suffer concussion or unconsciousness. When, however, a person knocked off a bicycle strikes his head on solid cement that does not yield, he may suffer fracture of the skull, concussion, hemorrhage, and possibly even death. In these circumstances the head is decelerated in a matter of a hundredth of a second or less, depending on whether the falling person has on his head a soft felt hat or a football helmet. Crash helmets to minimize sudden deceleration of the head are now in use in almost every military aircraft, since pilots, unfortunately, are unable to occupy rear-facing seats with present flight equipment.

Mr. Hugh De Haven, director of crash injury research at Cornell University Medical College in New York, is, among others, responsible for stressing these considerations. In this connection, one of his most impressive studies has been the analysis of nonfatal suicide leaps in the city of New York. Persons have survived virtually uninjured after leaps from the 10th and even the 17th floor of New York buildings, and, when the circumstances are analyzed in any given case, it turns out that the intended suicide victim has usually landed flat on his back in a soft garden plot or on a ventilating screen, or his fall may have been broken by awnings or an automobile top. This again indicates the importance of gradual rather than abrupt deceleration. These principles have proved to be immediately applicable not only in aircraft design but also in the automotive industry. A summary of these considerations has been given in Hugh De Haven's "Development of Crash-Survival Design in Personal, Executive and Agricultural Aircraft." [16]

The literature of aviation medicine, the great part of which has come from military installations, affords many other examples of material that is immediately applicable to commercial aircraft and to the automotive industry. It stresses the importance of having men of vision, imagination, determination, and sound training in the medical departments of all our military services, for the contributions they make are likely to be of importance not only to military operations but to society in the broadest sense.

SUBMARINE MEDICINE

Submarine medicine offers many examples of scientific disclosures with general application, but they are of less immediate significance to the civilian public at the present time, since it is not much given to traveling in submersibles, except for a few hardy souls such as William Beebe, who study marine life at great depths in the sea, and the "frogmen," who do mysterious things at depths of 100 or more feet in the interests of national defense. Of course, the diver and the caisson worker can always learn much from submarine experience, especially about protection from caisson disease and diver's "bends." There is no journal of submarine medicine, but the physiological problems encountered by submarine personnel are numerous and the literature pertaining thereto has been analyzed, summarized, and systematically arranged in a remarkable bibliography by Commander Ebbe C. Hoff, USNR (MC)[17] entitled "A Bibliographical Sourcebook of Compressed Air, Diving and Submarine Medicine," published by the Navy Department through the Government Printing Office in February, 1948. The bibliography contains nearly 3,000 entries, each of which is summarized and reviewed in subject groups. It does not fall within the scope of this paper to discuss the technical phases of submarine medicine but attention should be directed to K. E. Schaefer's comprehensive monograph (826 pp.) on German submarine medicine.[18] Dr. Schaefer, chief of the Submarine Physiological Laboratory at Heidelberg during the war, is now continuing his important studies in the physiology branch of the U. S. Naval Medical Research Laboratories at New London, Conn. His recent reports from the submarine base should also be consulted.

[18] Schaefer, K. E.: Symposium on Submarine Medicine, U. S. Fleet Naval Forces, Germany, Technical Section (Medical), 1950.

In closing this historical survey on the importance of military medicine to national and civilian defense I can do no better than to quote the words of Capt. J. S. Taylor, USA (MC), written after World War I: [19] "The world is far from even apprehending what it has yet to learn thoroughly, that in the field the distribution of medical supplies, prompt évacuation, skillful first aid, shelter, food, and restoratives available early for every fallen combatant are of infinitely more importance than highly technical relief to difficult cases. More critical still are the problems relating to later demobilization, to hospitalization and rehabilitation of war victims, and the faithful but well-ordered and economical relief of the wreckage of war. Millions will be spent and more millions wasted until the time comes when it is a recognized part of the program of national defense to organize methods of post bellum relief at the same time that activities are initiated for the prosecution of hostilities. We have progressed from the day of medical attendance for leaders to medical attendance for all combatants, and leaders are increasingly alive to the immediate necessary needs of their forces; but we have not yet attained to a comprehensive grasp of the requirements or possibilities of military medicine."

RADIATION PROTECTION COMES OF AGE

Richard H. Chamberlain, M.D., Philadelphia

There is now a large body of information regarding the hazards to human beings from ionizing radiations derived from x-ray sources, radioactive substances, particle accelerators, and nuclear fission.[1] There is also a wide appreciation of the need for intelligently applied protective measures, and for special training of those to whom the responsibility for protection is delegated. The fact that ionizing radiations produced reactions in living tissues was appreciated within a very short time after the discovery of x-rays and radium, but knowledge of the extent of the hazards and the degree of protection required was slowly accumulated over the first 35 years of this century. Knowledge depended on the evolution of the physics of radiation and the development of precise and sensitive instruments for measurement as well as the long latent period involved in biological responses to radiation.

By 1935 a new era in radiation protection became possible. The international acceptance of the roentgen as the unit of ionizing radiation made it possible to specify the amounts of radiation that were permissible. Instruments with stable and reproducible ionization response made it possible to measure the amounts received. The accumulation of radiobiological data furnished enough information to specify reasonable maximum permissible exposure levels. All three of these considerations have been subjected to even more intensive study in the recent past and furnish logical support for answers to the classic questions: 1. What is hazardous radiation, requiring protective measures? 2. Who should be protected? 3. How can protection best be achieved?

There is need for the application of some common sense in defining what constitutes hazardous radiation. A good deal of ungrounded fear has been generated in concern over the potential dangers associated with the development of atomic energy and the increasing medical uses of radiation. It seems reasonable to state that the hazards from these sources have been far less than the benefits derived in the form of increased awareness of the problem. The few accidents that have occurred in work with atomic energy have been limited to quite restricted situations in which the dangers were fully realized and the risk of these was unavoidable in accomplishing definite goals.

In medical use, standards of good protection practice have constantly improved and the majority of untoward exposures have been associated with risks purposefully encountered in the need for diagnosis of or treatment of disease by radiation methods. There is room for improvement, however, and so much of the responsibility for bringing about good practice of radiation protection depends on the medical profession that particular attention to universal acceptance of high standards is indicated. The increasing industrial use of radiation has also generally been accompanied by awareness of the protection problems and by good safety records.

The exposure of human beings to any unnecessary radiation is not to be encouraged; when no benefit can be expected, some exposures can be categorically forbidden. A situation of this type exists in the use of x-ray fluoroscopes for shoe-fitting, inasmuch as competent orthopedic authorities state that no benefit is to be achieved by their use in fitting shoes. Yet, one must be aware of the daily exposure of all human beings to measurable levels of ionizing radiations in the form of cosmic radiation and the emissions of natural radioactive substances, such as potassium 40, carbon 14, and radon, which are natural constituents of our environment, our food, and our bodies. We are also exposed to minute

amounts of radiation from luminous dial watches and clocks and certain types of eyeglass lenses, and still smaller amounts from other appurtenances of modern civilization such as projection television apparatus and the cumulative effects of the release of atomic energy.

WHAT CONSTITUTES A RADIATION HAZARD

The problem, then, of what constitutes a radiation hazard, is one of degree and quantity. By international agreement, the maximum permissible exposure, to the whole body or gonads, has been set at 0.3 r per week measured in free air (0.5 r on the body surface) or, in the the case of the hands and forearms, at 1.5 r per week. Both of these refer to externally originating x-rays or gamma rays of quantum energy less than 3.0 mev. Appropriate physical and biological equivalents are used for other forms of ionizing radiations. These recommendations are made for use in unavoidable exposure for adequate reasons and do not imply either that they limit the use of higher levels for good and sufficient cause, as for medical diagnosis or treatment, or that the least possible exposure should fail to be the goal at all times. They presume that the exposures may be repeated in regular occupation. The recommendations are based on the pooled opinions of experts forming the National Committee on Radiation Protection and the International Commission on Radiation Protection and embody the best knowledge currently available of skin, whole body, gonad, and blood responses of human beings and experimental animals as well as special consideration of the relationship of radiation to gene mutations and to the production of carcinoma and leukemia.

In making use of these recommendations, it is still necessary to apply interpretation of the degree of need for a particular radiation exposure as well as considerable skill in the measurement of the physical factors that will deliver it. This requires understanding by informed personnel, applied with common sense, and, as we shall discuss later, usually the decision must be made by the actual user of the radiation.

WHO SHOULD BE PROTECTED

The question as to who should be protected would seem to be an easy one, but the answer is influenced by the foregoing examination of the useful purpose gained by the exposure. At one extreme might be placed the medical patient with malignant disease in which cure or at least palliation of the disease might be expected. In this instance, normal considerations of protection must be foregone. While it is still desirable to give as little radiation as possible, the treatment may be carried to the point just short of where the acute effects of the radiation are as dangerous to the patient's life as the malignant disease. This is in the order of 1,000 times the general level of exposure expressed in the maximum permissible exposure recommendations. Strict comparisons with maximum permissible exposure values cannot be made because of the time factors and repetition involved, but are used here to indicate the quantities in general terms. In roentgen diagnosis, the judgment as to how much radiation may be employed is best individualized in each instance, but it never should reach the dosages used for malignant disease. Even for exceptional situations diagnostic uses do not usually exceed 10 to 50 times the weekly maximum permissible exposure and are not repeated without adequate indication.

At the other extreme one should consider the "innocent bystander" and the public at large. For no better reason than that nothing useful is derived from their exposure to radiation, this is the group that should receive the least. Yet, the natural radiation sources combine to produce exposures of a probable maximum of 0.015 r per week, or about 1/20 of the maximum permissible level. The only known potential hazard of doubling or tripling this unavoidable radiation is the genetic one, for which precise information is not currently available, but it merits attention in any measure that might appreciably raise the natural exposure of the general population. The potential genetic dangers should also be considered in all uses of radiation, and special shielding or other protection is desirable wherever it can be employed.

It is the group that fits into neither of the previous categories that is most difficult to define, and, to my best knowledge, no satisfactory statement of what constitutes a "radiation worker" has been offered. In actual practice, most persons who are employed in the vicinity of radiation sources and have something to do with them receive about 0.03 r per week, which seems to be a reasonable and not excessive increase over the natural background. Certainly, every effort should be made to keep radiation exposures to levels of this order. If, however, one has adequate knowledge of the dangers, cannot reasonably avoid them, and is doing so for a meritorious purpose, judgment may allow the overriding of standard recommendations. In almost every instance of this type, however, it will be found that exposures can be brought to within the recommended amounts by the use of better technical procedures, and the greater one's knowledge of the hazards becomes, the more effort will be expended in achieving such improvements. Similar situations may be encountered in atomic warfare and the military use of atomic energy. Nevertheless this should not lessen the force of the standard recommendations.

HOW TO PROVIDE RADIATION PROTECTION

In establishing how to provide radiation protection, the data that have been collected and disseminated are brought into good practical application. This has been carried to a high degree of usefulness in medical radiology, industry, and atomic energy facilities by cooperation and individual initiative. As with all safety measures, new methods are constantly being introduced, and some procedures always need revising to bring them up to the best standards. The effectiveness of protection in the United States is due to three factors: (1) information, basic and applied; (2) education and professional standards; and (3) methods of good practice.

Basic and Applied Information.—Information has been accumulated and tirelessly disseminated in recent years by the National Committee on Radiation Protection, articles in pertinent professional and technical publications, and the Atomic Energy Commission. Detailed descriptions of the hazards involved in the complete spectrum of radiation sources, applied data for special uses, and methods for use, protection from, and disposal of radioactive materials can usually be found in the handbooks published through the Bureau of Standards and the United States Government Printing Office for the National Committee on Radiation Protection. This committee, and its subcommittees for each handbook, have been composed of the best available experts from medical, industrial, physical, and governmental sources for each topic. They have elaborated on the recommendations of the International Commission on Radiation Protection and cooperated with it. These handbooks constitute a satisfactory code of good opinion and usage and have been used not only by private and industrial workers but also by the Atomic Energy Commission and other governmental agencies. Problems not covered in these publications are usually highly specialized and can be derived from them or found in publications from other sources.

Education and Professional Standards.—As with other advanced technical activities that require intelligent judgment, education and professional standards offer the only valid method of ensuring good practice. The interpretation of the general rules or pattern of protection in the individual case cannot be achieved through legislation or the issuing of licenses. In general, competency depends on the education and experience of the user. In medicine, exceptional qualifications in these respects are attained by the radiologists in their training in radiation physics and radiobiology and by the group of radiological physicists that collaborates with them. Both of these are eligible for certification by the American Board of Radiology on attainment of proficiency and adequate background in these respects. Other physicians who need to use radiation in certain fields can and should receive training in the special problems of radiation protection. To omit this important training for even the use of chest fluoroscopes or occasional radiography is the equivalent of omitting the basic training in any of the medical fields in preparation for the use of life-giving but potentially dangerous agents. The trend in medicine is toward the centering of the management of radiation-producing materials in the hands of certified radiologists, or at least to the supervision of the protective aspects by such specialists and their co-workers in radiological physics. Obviously others who demonstrate sufficient knowledge and experience should also be permitted to work with radioactive materials.

For use in man of radioactive isotopes produced by or obtained through the Atomic Energy Commission, a special form of control has been derived from the provisions of the Atomic Energy Act. This legislation requires the Atomic Energy Commission to ensure that proper safety and health precautions are employed as a requisite to obtaining of radioactive isotopes from the commission. Recognizing the difficulty of decisions for both medical and other uses, the Atomic Energy Commission has used committees of specialist consultants in helping with the evaluation of applications from the standpoint of health and safety. In practice, it has evolved that the initial judgment can be based on education and experience, the reasonableness of the use and dosages proposed, and the adequacy of physics consultation and instrumentation. Nevertheless, the final execution of adequate protection depends on the local situation and, because of this, the further requirement of a local isotope committee composed of a suitable group of experts has been made, except for special situations where the use of the radioactive material has become well standardized and for applicants with previously demonstrated and well-proved experience. In major educational institutions with local committees of exceptional experience, and when the volume of uses of radioactive materials has been rather large, the determination of procedure for individual uses has been shifted to the local committee with the issuance of "general authorizations."

This pattern of committee approvals of the uses of radiation materials and sources has also been the basis for recent actions by the American Medical Association and the American Hospital Association in setting up methods for control of radiation protection in approved hospitals. In the employment of a special hospital committee that can investigate locally the adequacy of an installation and the qualifications of the user, the best practical method is likely to be obtained. The committee should consist of at least a radiologist, preferably a radiological physicist, and advantageously a hematologist or interested internist. For radioactive isotopes a biochemist or pharmacologist can contribute to the understanding of the safety factors.

In the Atomic Energy Commission and in industry, as well as in medicine and university centers, there has developed a group of safety and health consultants who do not have the medical experience of certified radiological physicists but whose primary concern has been the supervision of adequate radiation protection. Many of these workers are quite competent to control the physical aspects of the problem, particularly if they are working with committees as outlined above. A registry of such qualified consultants is currently being formed.

Methods of Good Practice.—The methods of good practice depend on the needs in the particular situation in which radiation is being used, be it for research, medical diagnosis or treatment, industry, Atomic Energy Commission, or military application. The general plan in setting up a program for radiation protection will probably follow along these lines: (*a*) formation of a well-informed and well-trained group or acquisition of the same information and training by an individual; (*b*) establishment of a well-designed and properly protected installation with good equipment; (*c*) initial inspection and testing of the safety of the apparatus and radiation sources; (*d*) appraisal of the indications and levels for radiation exposure of all persons, including "workers," patient, and the general public; and (*e*) establishment of a regular system of monitoring with safety and health consultations with competent physicists.

SUMMARY

With the increasing use of ionizing radiations, adequate knowledge of the nature of the hazards has been gained. Within reasonable limits, we now understand what constitutes hazardous radiation for which protection is required and have the instruments and units with which to measure it. Who should be protected and the degree of protection required depends on individual circumstances, but the least radiation that can be given is always the best. How to achieve adequate protection is best determined according to the education and experience of the user in consultation with suitable consultants and advisers. Local committee control with a good program of safety measures tailored to the particular situation seems to offer the best solution to maintaining good radiation protection in practice.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council has authorized publication of the following article.

RALPH E. DE FOREST, M.D., *Secretary.*

The Transistor Hearing Aid

A recent development in the electronic field is the transistor, a substitute for the vacuum tube. One application of the transistor is in the hearing aid. The Council on Physical Medicine and Rehabilitation anticipates that many transistor hearing aids will appear on the market; therefore a general statement on their merits and shortcomings is in order. Research on the transistor was carried out at the Bell Telephone Laboratories, and now several manufacturers are licensed to develop and produce transistors. Not all of the deficiencies associated with mass production of a new product have been overcome. Research is continuing.

There are three kinds of transistors: the junction, the alloy-diffusion junction, and the point-contact types. A typical form of junction transistor is a small rectangular block measuring 12 by 7 by 5 mm. Its longest dimension is actually no more than one-half inch, so that it is smaller than the miniature vacuum tube used in the conventional hearing aid. Three wires project from one end of the block. The middle wire is the *base* wire; it connects with a "positive germanium" area inside the block. This area is between two "negative germanium" areas. One of these two areas connects with the so-called *collector* wire, the other with the *emitter* wire.

Germanium is element 32 in the periodic table and is classified as a semiconductor. Its electric properties are strongly affected by impurities, so that germanium with small amounts of antimony or arsenic is called positive germanium, while germanium with small amounts of aluminum or gallium is called negative germanium. Elaborate theories explain the occurrences in the transistor, but the fact of practical importance is that, if a variable current is passed between emitter and base wires, corresponding variations are imposed on any current that may be passing between emitter and collector wires. In other words, the base current influences the collector current, and the effect is one of considerable amplification.

The junction transistor just described is also called the "n-p-n transistor," because the positive germanium is located between the negative germanium areas. Another kind is the point-contact transistor, which is not used in modern hearing aids.

The alloy-diffusion type of transistor is becoming more and more popular. It is a form of junction transistor and consists of a tiny pellet of negative germanium on one side of which is diffused a positive bead of indium (or gallium), with a similar bead of indium on the opposite side. The base wire is connected to the germanium. The emitter wire is connected to one bead of indium and the collector wire to the other. The germanium and indium, occupying a volume no more than 1 cu. mm., are sealed in plastic. The complete transistor, which has three wires extending from it, is no larger than a miniature vacuum tube.

The most important advantage of the transistor hearing aid is its economy of operation. The all-transistor hearing aid needs only one battery. The all-vacuum-tube hearing aid requires a B-battery and an A-battery. The A-battery heats the filament for electron emission, and the B-battery establishes the positive pole for the plate and is a source of power for acoustical amplification. The transistor has no filament, hence only one battery is required. Fortunately, this battery can be a 1.5 volt carbon-zinc dry cell or a small 1.2 volt mercury battery. In the vacuum tube, heating of the filament requires the most power. Since the transistor does not require heater current, obviously a large saving can be realized.

It is not known at present whether some of the shortcomings of the vacuum tube hearing aid will be eliminated by the use of transistors. It is conceivable that the noises resulting from thermal emission and from the movements of the filament, plates, and grids in the vacuum tube that are caused by mechanical shock can be minimized. On the other hand, additional background noises in the transistor may take their place.

At the present time, it appears that no significant change has been made in the size of the transistor hearing aids over the vacuum tube hearing aids. One would assume that with the elimination of a B-battery, the over-all size would be smaller; but this battery space is filled with other components of the transistor circuit that are needed for its operation. In time the transistor hearing aids may be lighter and smaller, but there is no significant change in the outward appearance at this time.

Since the hearing aid is a new application for the transistor, it is reasonable to expect that many deficiencies and shortcomings in performance will be encountered. The new components necessary to couple the transistors within the circuit may cause some trouble, but it is more than likely that the major failures will be in the transistor itself. The transistor is new, and not all of the imperfections have been eliminated. The hearing aid may appear to "sleep," that is, to act as though it had an open circuit or the battery were dead or as if it were not functioning at its original efficiency. In order to cover these insufficiencies, the purchaser should insist on a guarantee that the instrument will be maintained in top condition for at least one year and that all defective transistors will be replaced without cost.

There are three general types of transistor hearing aids known at this time. 1. The all-transistor type uses a crystal microphone, three transistors, a magnetic type earphone, and one low voltage battery with the necessary circuits. 2. The combination type consists of a crystal microphone, two vacuum tubes, one transistor, which takes the place of the power vacuum tube amplifier, a magnetic type earphone, and an A-battery and a B-battery with the necessary circuits. 3. The single transistor type consists of a carbon-granular microphone (a telephone type of transmitter), one transistor, a magnetic type earphone, and a low voltage battery plus the necessary circuits. This instrument obtains its amplification in part from the transistor and in part from the carbon-granular microphone, which in itself is an amplifier.

The most important advantage of the transistor hearing aid that can be claimed at the present time is a significant reduction in operational cost, as much as 80% and perhaps more. At present it seems that the size and weight of the hearing aid will not be changed appreciably. There does not seem to be any significant improvement in amplification, in tone quality, or in fidelity of the transistor hearing aid over other kinds. The purchaser should insist on a written guarantee to cover possible mechanical and electrical defects in the instrument.

THE WORLD MEDICAL ASSOCIATION AND MEDICAL EDUCATION

Under the auspices of the World Medical Association there was held recently in London a conference on medical education. This was unique because it was the first world conference on this subject. Collaborating with the World Medical Association were the World Health Organization, the Council for International Organizations of the Medical Sciences, and the International Association of Universities.

The first World Conference on Medical Education was a notable event for the World Medical Association and for medical education. For the World Medical Association it demonstrated the capacity of this organization to organize a major international conference that was hailed by all who attended it as being outstanding for its broad and fundamental approach to the subject under discussion and for the quality of the papers and discussions presented.

For medical education, the conference made it clear that medical schools throughout all parts of the civilized world have the same fundamental problems. Basic concerns of medical educators from Asia, Europe, the United Kingdom, Latin America, Australia, and North America were almost indistinguishable. All recognized the difficulty of accommodating in an already overcrowded curriculum the rapidly growing body of fundamental medical knowledge. Apparently in every part of the world students are being forced by the pressures of the amount of material to be covered to too early specialization in their studies to the neglect of the humanities, the social sciences, and indeed to the broader aspects of medicine itself.

The desire for more effective integration of the various subjects taught in medical school appears to be the monopoly of no country. Also, the conference brought out the fact that there is universal recognition of the need for more stress on preventive and social medicine in the education of physicians.

No dissent was heard from any quarter to the description of the type of person who makes the ideal medical student as so delineated by Sir Lionel Whitby, president of the conference. There was general concern, however, that medical schools may forget that the medical student is a human being with most of the frailties and limitations of his species. The difficulty of selecting the most promising students from among the large number of applicants who seek to study medicine is apparently a world-wide problem. No country claimed that it has found a satisfactory answer to the problem, although experience and experiments with many different methods of selection were reported.

In keeping with the spirit of the conference, no resolutions were passed, and no programs were formulated or adopted. The conference adhered strictly to the concept that it was to provide an opportunity for free exchange and discussion of ideas and experiences. Those who attended the conference agreed that its most important effect would be to strengthen the faith of medical educators in the basic ideals of medical education and that the spirited discussion of these ideals and of the best ways of achieving them would furnish motive power for further advances in medical education in all countries represented at the conference.

The most convincing evidence of the success of the meeting was the spontaneous expression by those in attendance of the hope that another conference of the same type would be held again as soon as practicable so that the momentum of international exchange and discussion so well initiated by this conference would not be lost.

The British Medical Association acted as the host organization, and other groups served as benefactors by providing contributions to help meet the expenses for this conference. Included are firms the names of which are very familiar to American physicians, e. g., Abbott Laboratories, American Home Products, Burroughs Wellcome, Ciba, Parke Davis, Pfizer, Sharp & Dohme, R. P. Sherer, Gelatin Products, and Wyeth. Other organizations, from the United Kingdom and the European continent, indicated their desire to support the conference. Among the foundations providing money were Pfeiffer Research Foundation, Lasdon Foundation, National Foundation for Infantile Paralysis, and the Wellcome Foundation. The United States Public Health Service also contributed generously.

Other names could also be mentioned for their relation in the program and its organization, but they would only emphasize further one point—the broad interest shown in the conference. It is not easy to arrange such a gathering of talent from throughout the world and to provide facilities for meeting plans, but it was done splendidly, and everyone who had some part in making the conference possible can be pleased with the results of their efforts and the appreciation held by all visitors.

The setting for the meeting was aptly expressed by Sir Lionel Whitby. He wrote: "Many of us are convinced that the dominant problem facing the medical profession in the second half of the twentieth century is, the problem of medical education. In an age of ever-increasing scientific advance and ever-increasing specialisation of knowledge, how can we best teach the young men and women who will be our successors as the doctors of the future? What are to be the subjects? What are the principles that should guide us?

"It is the purpose of this conference not to give any final answer to these fundamental questions, but to explore the situation as we find it in this year 1953. The object of the conference is to provide an opportunity for the interchange of thoughts and experience by the doctors of many lands so that we can shape the future development of undergraduate medical education."

This challenge was accepted enthusiastically by men and women interested in medical education in many countries. Those who gave papers and led discussions represented countries too numerous to mention. Participation by the several hundred visitors was made pleasant and productive through the use of the three official languages of the World Medical Association, Spanish, French, and English. Of no small interest were the social events and technical exhibits.

Some of the papers offered at the conference and a summary of the proceedings appear in the August 29, September 5, and September 12 issues of the *British Medical Journal*. All of the papers and much of the discussion will be published in the future by the Oxford University Press under the general editorship of Dr. Hugh Clegg, who is the editor of the *British Medical Journal*. Orders for the proceedings were taken at the conference but may also be sent to the publisher and to the office of the editor.

The first world conference on medical education reflects unequivocally the farsighted objectives of the World Medical Association. Unlike the World Health Organization, which represents the governments of the member countries, the World Medical Association represents the voluntary medical organizations in more than 40 countries. Its influence already has been felt in several quarters, and as it continues to grow it will be even more effective as a voice for doctors as a whole throughout the world. Those who have watched this organization from its beginning have seen it develop within less than a decade into a watchful, fact-finding, and, when necessary, hard-hitting body. Twice a year the council of the World Medical Association meets to consider many problems, and once a year there is a general assembly where representatives from member countries can act on these problems. Each year the assembly meets in a different city. In 1952 it met in Athens, in 1953 in The Hague. In 1954 the assembly will convene in Rome. Between now and then physicians and their friends can make plans for the conference in this fascinating city with its background of cultural interests. Details will appear in later issues of THE JOURNAL, but they can also be obtained from the office of the Secretary-General, Dr. Louis H. Bauer, 345 East 46th Street, New York, N. Y.

BEHAVIOR CHANGES IN CHILDREN SUBJECTED TO TONSILLECTOMY

During a period of three years Jackson and her associates [1] observed a group of 140 children aged 3 to 8 years before and after they were subjected to tonsillectomy in an effort to learn whether and under what circumstances this surgical experience was associated with behavior changes that indicated emotional trauma. They devised a method of study that consisted of conferences between a psychiatric social worker and the mother and child, at which time certain facts about the child's behavior and emotional status were determined. The interviews took place before tonsillectomy, in the period immediately after the surgical procedure, and after a lapse of three months. The information obtained during the various interviews was then studied by a committee consisting of three pediatricians, the social worker who conducted the interview, and the anesthetist in attendance at the operation. In addition, two psychoanalysts, a psychologist, and a public health pediatrician served as consultants to the committee. The children were operated on by one of three otolaryngologists at one of three hospitals. About half the children were anesthetized by a person who possessed both special knowledge and experience in emotional problems as well as extensive skill and training in the field of anesthesia.

In more than 50% of the children behavior either improved or showed no change, while in 30% of the group there was improvement in some traits and disturbance in others. In most instances mothers considered the behavior of the children to have improved after the tonsillectomy procedure, although in a few cases some of the behavior disturbances appeared to outweigh the general trend toward improvement. Of the entire group of 140 children, behavior changes indicative of emotional trauma occurred in 13. In general, it was revealed that children who were treated considerately as patients and those who had not been exposed to previous episodes of emotional trauma showed less evidence of emotional trauma after tonsillectomy. The youngest children in the group manifested more, albeit milder, adverse alterations in behavior. Interestingly enough, 91% of the entire group of 140 children were either benefited or scarcely affected by the tonsillectomy procedure. In general, this study suggests that considerate and compassionate management of young children who are subjected to tonsillectomy will restrict behavior changes attributable to the surgical experience to a minimum.

---

[1] Jackson, K., and others: Behavior Changes Indicating Emotional Trauma in Tonsillectomized Children. Pediatrics 12:23 (July) 1953.

ORGANIZATION SECTION

ST. LOUIS CLINICAL MEETING, DEC. 1-4

Final details for the Clinical Meeting in St. Louis are almost completed. The program of clinical presentations will be outstanding, with lectures by prominent physicians from all parts of the country. The Scientific Exhibit will be correlated as far as possible with the clinical presentations. There will be several special features in addition, however, which will attract much attention.

Diabetes

The subject of diabetes will be presented under the auspices of the Joslin Clinic, New England Deaconess Hospital, Boston, and the St. Louis Diabetic Association. The chairman is Howard F. Root, M.D., Boston. A large exhibit will present data regarding the prolongation of life derived from the follow-up of many thousands of cases, with the causes of death in 12,000 cases. Prevention and treatment of toxemia in pregnant diabetics will be shown, together with the classification of pregnant diabetics for decision as to hormonal therapy, with the mode and date of delivery. Other factors include the treatment of coma and the prevention of degenerative sequelae in eyes, arteries, and kidneys.

Associated with the exhibit in an adjoining room will be a question and answer conference on diabetes daily from 10:00 a. m. to 1:00 p. m. beginning Tuesday morning and ending Friday at 12:00 noon. Twenty-minute discussion periods with questions and answers will be conducted according to a prearranged schedule, covering all phases of the diabetes problem. Among the discussants will be Howard F. Root, M.D., Boston; Robert McElvain, M.D., St. Louis; John L. Kennedy, M.D., St. Louis; George Mahe, M.D., St. Louis; Priscilla White, M.D., Boston; William H. Olmsted, M.D., St. Louis; Joseph C. Edwards, M.D., St. Louis; Sallie Wood, St. Louis; Henry E. Oppenheimer, M.D., St. Louis, and E. Paul Sheridan, M.D., Denver. Many patients will be presented to illustrate various points emphasized by the speakers.

Prevention of Traffic Accidents

An exhibit symposium on the prevention of traffic accidents will combine the experiences of the police, the Safety Council, and the medical profession. The following topics are on the program. Attendants will be present continuously throughout the week to demonstrate and answer questions:

Human Ingredient in Traffic Accidents.
  JACOB KULOWSKI, M.D., St. Joseph, Mo.
Testing the Drinking Driver.
  HERMAN A. HEISE, M.D., Milwaukee, Committee on Tests for Intoxication, National Safety Council, and Committee on Medicolegal Problems, American Medical Association.
Traffic Accidents Can Be Prevented.
  HUGH H. WAGGONER, Missouri State Highway Patrol, Jefferson City, Mo.
Safety Educational Program.
  DAVID M. BALDWIN, National Safety Council, Chicago.
Crash Injury Research.
  INDIANA STATE MEDICAL ASSOCIATION AND INDIANA STATE POLICE, Indianapolis.
The Physician's Responsibility in the Prevention of Traffic Accidents.
  CAREY N. MOON, M.D., FLETCHER D. WOODWARD, M.D., and EDWARD L. COREY, M.D., University of Virginia School of Medicine, Charlottesville.

Problems of Delivery

Manikin demonstrations on problems of delivery will be presented by an outstanding group of obstetricians in a room adjoining the Scientific Exhibit. Demonstrations will be conducted on Tuesday and Wednesday at 10:00 a. m., 12:00 noon, 2:30 p. m.; on Thursday at 12:00 noon, 2:30 p. m., and 4:30 p. m., and on Friday at 10:00 a. m. Richard Paddock, M.D., St. Louis, is the chairman.

Fractures

The fracture exhibit, which has long been a feature of the Scientific Exhibit, will cover fractures resulting from a fall on the outstretched hand, fractures of the lower end of the radius, and fractures of the ankle. The committee in charge will be Gordon M. Morrison, M.D., Boston, chairman; Ralph G. Carothers, M.D., Cincinnati, and Herbert Virgin Jr., M.D., Miami, Fla. They will be assisted by a large group of surgeons experienced in the treatment of fractures.

"MARCH OF MEDICINE" SERIES

Research and treatment of heart disease will be the subject of the first program of "The March of Medicine" television series being launched Oct. 8 over the National Broadcasting Company TV network. Over 70 stations in the United States and Canada will carry the progress report on study of coronary artery disease and hypertensive heart disease. The telecast will originate in Boston, Thursday, Oct. 8, at 10 p. m. (EST). Television audiences will find local time and channel in newspaper advertisements in cities carrying the programs. The medical profession has been informed of the TV series through announcements mailed by Smith, Kline & French Laboratories, the sponsor and producer.

The three-program series, produced in cooperation with the American Medical Association, is designed to give the public better insight into some of the nation's major health problems. Actual live presentations will be telecast from some of the leading medical centers in order to create greater public awareness of the extensive research being carried out by the medical profession.

The second in the fall series, on Nov. 5, will feature the tremendous effort and study being undertaken in the fight against cancer. Highlights of medical progress as reported at the A. M. A. Clinical Meeting in St. Louis will be televised in the third program Dec. 3. Cooperating in the Oct. 8 telecast will be members of the staffs of several hospitals in the Boston area, associated with Harvard Medical School, Boston University School of Medicine, and Tufts College Medical School. Among physicians appearing will be Herrman L. Blumgart, M.D., professor of medicine, Harvard Medical School; Howard B. Sprague, M.D., clinical associate in medicine, Harvard Medical School; Paul D. White, M.D., consultant, Massachusetts General Hospital; and Robert M. Wilkins, M.D., associate professor of medicine, Boston University School of Medicine.

REPORT ON GRIEVANCE COMMITTEES

Just off the presses is a detailed report on county medical society grievance committees. Prepared by the A. M. A.'s Council on Medical Service, this study deals with the organization, functions and operations of 198 mediation committees throughout the country. To make the data of more practical value, the societies have been divided into groups according to size. Copies are available from the Council (see page 510).

PR CONFERENCE IN ST. LOUIS

The A. M. A.'s sixth annual National Medical Public Relations Conference will be held Monday, Nov. 30.—the day before the opening of the Clinical Session—at the Jefferson Hotel, St. Louis. The Conference program will be geared primarily for physicians. Members of the House of Delegates, officers of state and county medical societies, officers of the Association and executive secretaries and PR personnel are cordially invited.

MEDICAL NEWS

CALIFORNIA

City of Hope Plans Expansion.—At its recent anniversary convention at the Ambassador Hotel, Los Angeles, the City of Hope (formerly the Los Angeles Sanatorium in Duarte) adopted a budget of $6,800,000 to carry on for the next two years. This budget, an increase of 2 million dollars over the 1951-1953 period, will permit the medical center, a nonprofit organization for the treatment of tuberculosis and cancer, to broaden its research and training program and will establish the groundwork for the creation of a new medical college at the City of Hope.

CONNECTICUT

Hospital News.—Dr. H. Edward MacMahon, professor of pathology, Tufts College Medical School, Boston, will give an address entitled "Liver Changes in Biliary Xanthomatosis" at Hartford Hospital, Oct. 10, 11 a. m.

General Practitioners Meet in Hartford.—The annual scientific assembly of the Connecticut chapter, American Academy of General Practice, will convene at the Hotel Bond, Hartford, Oct. 8, under the presidency of Dr. Edwin R. Connors, Bridgeport. The following program will be presented:

Peptic Ulcer, Samuel F. Marshall, Boston.
Headache—As the Neurosurgeon and the General Practitioner See It, J. Rudolph Jaeger, Philadelphia.
Management of Common Gynecological Problems, Walter J. Reich, Chicago.
Management and Diagnosis of Tumors of the Liver, George T. Pack, New York.
Diagnosis and Treatment of Acute Cardiovascular Emergencies, Joseph B. Vander Veer, Philadelphia.
Diagnosis and Treatment of Psychosomatic Disorders, Edward Weiss, Philadelphia.

A cocktail hour, 6:30-7:30 p. m., will precede dinner, after which Dr. John S. DeTar, Milan, Mich., will discuss "What the Academy of General Practice Means to the General Practitioner."

DELAWARE

State Medical Meeting at Wilmington.—The Medical Society of Delaware will hold its annual meeting at the Hotel DuPont, Wilmington, Oct. 12, under the presidency of Dr. Victor D. Washburn, Wilmington, who will deliver the presidential address, Wednesday, 11:30 a. m. On Tuesday, the annual reception and dinner will be followed, at 9 p. m., by an address by Dr. Thomas H. Alphin, Washington, D. C. Presentations at the scientific session include:

Daniel J. Preston and John W. Alden Jr., Wilmington, Incidence of Common Bile Duct Disease Following Surgical Exploration.
R. Douglas Sanders, Wilmington, Anesthesia Services in Delaware.
Harold S. Rafal, Wilmington, Report on Cancer Detection to the Physicians of Delaware.
Anthony F. DePalma, Philadelphia, Frozen Shoulder.
Richard A. Neubauer, Wilmington, Importance of Body Fluid and Electrolytes in Clinical Medicine.
Harold W. Lovell, New York, Abuse of the Barbiturates.
Hon. Thomas Herlihy Jr., Wilmington, Legal Aspects of the Barbiturate Problem in Delaware.
Cazivlle L. Hudiburg, Wilmington, American Medical Education Foundation.
Philip B. Gordy, Wilmington, Diagnosis and Treatment of Spontaneous Subarachnoid Hemorrhage.
William Likoff, Philadelphia, Treatment of Cardiac Emergencies.
William T. Green, Boston, Early Management in Poliomyelitis.
Chauncey L. Palmer, Pittsburgh, Medical Care Program for the Indigent in Pennsylvania.
Mark V. Ziegler, Baltimore, Administration of a Medical Care Program by the Maryland State Department of Health.
J. Wilfrid Davis, Baltimore, Baltimore City Medical Program.

ILLINOIS

Meeting to Honor Dr. Ciocatto.—The Illinois and Chicago societies of anesthesiologists will honor Dr. Enrico Ciocatto, professor of anesthesiology, University of Turin, Italy, at a buffet dinner and meeting at the Tally Ho room of the Sheraton Hotel, 505 N. Michigan Av., Chicago, Oct. 10, 6:30 p. m. Dr. Ciocatto, a native of Oklahoma, is editor-in-chief of the *Minerva Anesthesiologica* (Italian journal of anesthesiology). For reservation send check ($4.50), together with stamped, self-addressed return envelope, to Dr. Huberta M. Livingstone, 5805 Dorchester Ave., Chicago 37.

Award for Surgical Research.—The Chicago Surgical Society announces that the 1954 Nelson M. Percy award of $500 for surgical research will be made by Dr. Nelson M. Percy at the April or May meeting of the society. Contestants must reside in Cook County and be preparing for a surgical career. Members of the society are not eligible for the award but may be co-authors of the manuscript. A preliminary abstract of the work should be submitted to the secretary (Dr. Earl Garside, 5153 N. Clark St., Chicago 40) as soon after Oct. 1 as possible. The work must not have been previously published, but it may be presented at other meetings during the year, after the November meeting of the society, and may be submitted for publication, provided that the publication date is after the May meeting. At the time of presentation of the preliminary abstract the secretary should be informed of plans for other presentations and for publication.

Chicago

Free Lecture Series.—The Museum of Science and Industry, 57th and Lake Michigan, announces the following free lectures, Sundays, 3 p. m.:

Oct. 4, Skin Blemishes and Their Treatment, Herbert Rattner.
Oct. 11, Reducing Can Be Fun, Clifford J. Barborka.
Oct. 18, The Successful Marriage, Roland P. Mackay.
Oct. 25, How Old Are You? Morris Fishbein.

Dr. Goldblatt to Lecture at Mount Sinai.—The recently completed research laboratory and professional services building of the Mount Sinai Hospital of Chicago (*J. A. M. A.* **152**:616 [June 13] 1953) will be opened for the medical profession, on Oct. 7, with an open house, beginning at 1:30 p. m. At 4:30 p. m. Dr. Harry Goldblatt, director of laboratories and research, Mount Sinai Hospital, Cleveland, will deliver the dedicatory address "Present Status of the Renal Origin of Essential Hypertension."

INDIANA

Gift to University.—Dr. Goethe Link, Indianapolis, has given to Indiana University, Bloomington, his country home and 49 acres of land adjoining the university's Link Observatory property northwest of Martinsville.

Society News.—Dr. Robert A. Smith, New Castle, has been named president of the Indiana Academy of Ophthalmology and Otolaryngology; Dr. Cecil P. Clark, Indianapolis, president-elect; Dr. Raymond R. Calvert, Lafayette, vice-president; and Dr. John R. Swan, Indianapolis, secretary-treasurer.

Health Forums.—The Vanderburgh County Medical Society and the Evansville *Press* will present a series of free Sunday night public forums on health and medicine in Bosse High School auditorium, Evansville, Oct. 4, 11, 18, and 25, Nov. 1, 8, and 29, and Dec. 6. More than 70 members of the society indicated their willingness to appear on the panels.

Personal.—Dr. Marshall I. Hewitt, South Bend, has joined Parke, Davis & Company, Detroit, where he will be engaged in editing medical literature and other material for the information of physicians.——Dr. Lloyd W. Hisrich has been appointed secretary of the Batesville Board of Health.——Dr.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Dulania S. Wiggins, New Castle, has been named full-time physician for the Indiana Village for Epileptics.——Dr. Roscoe L. Sensenich, South Bend, past president of the American Medical Association and the Indiana State Medical Association, will head the state-wide fund raising drive of the Indiana division of the American Cancer Society.——Dr. Roscoe S. Yegerlehner, Kentland, has been made a member of the Kentland-Jefferson Consolidated School Board.——Dr. James S. McBride, Indianapolis, was honored for 30 years of antituberculosis work at the annual meeting of the Marion County Tuberculosis Association, when he was given the Mary A. Meyers Memorial Award.——Dr. Donald J. Caseley, formerly medical director of the Indiana University Medical Center, has been appointed medical director of St. Luke's Hospital in Chicago.——Dr. John H. Green, North Vernon, is retiring from the practice of medicine to become director of the clinical department at Muscatatuck State School, Butlerville. Dr. Green, who has practiced 42 years in Jennings County, was formerly president of the State Board of Health and has served as both city health officer and county health commissioner.——Dr. Mary Elizabeth Miller Genna, Indianapolis, has been appointed director of the Student-Employe Health Service at Indiana University Medical Center to succeed Dr. Harold N. Johantgen, who has gone into private practice at Shelby, Ohio. Dr. Genna was a member of the Student Health Service staff on the Bloomington campus for the past five years.

MICHIGAN

Triennial Reunion of Alumni.—The fifth triennial reunion of medical alumni of the University of Michigan Medical School and former members of the University Hospital staff will be held in Ann Arbor, Oct. 15-17. There will be a two day scientific session, with clinical conferences, a symposium on poliomyelitis, and other symposiums covering a variety of medical problems; on the third day there will be a special convocation of the medical school in the morning, and the Michigan-Northwestern football game in the afternoon. Details may be obtained from Dean Albert C. Furstenberg, 123 West Medical Building, University of Michigan, Ann Arbor. Headquarters for the meeting will be the Horace H. Rackham School of Graduate Studies. Registration fee is $5.

NEW JERSEY

Postgraduate Courses.—The Passaic County Medical Society is sponsoring a series of Friday lectures (4-6 p. m.) on office proctology, with Dr. Rudolph V. Gorsch, adjunct professor of proctology, New York Polyclinic Medical School and Hospital, as lecturer. A course in cardiology for general practitioners is offered on Tuesdays (4-6 p. m.). Courses will be held in the society building, 625 Broadway; fee, $50 per course. Details may be had from Dr. Wayne W. Hall, 515 Broadway, Paterson.

Dr. Bunnell to Give Albee Lecture.—In an all-day program on surgery of the hand, the second Fred H. Albee annual lecture on rehabilitation will be delivered at the Kessler Institute for Rehabilitation, West Orange, on the morning of Oct. 8, by Dr. Sterling Bunnell, San Francisco, who will speak on tendon surgery of the hand. Four panels have been planned for the afternoon. Dr. Edward J. Flynn, Boston, will speak on acute hand injuries (1-2 p. m.); Dr. J. Leonard Goldner, Durham, N. C., on reconstruction of the hand following cerebral palsy and traumatic spastic paralysis (2-3 p. m.); Dr. J. William Littler, New York, on phalangization (3-4 p. m.); and Dr. Jerome Gelb, Newark, on cineplasty in children (4-5 p. m.). Dr. Bunnell will summarize the program at the end of the day. Among the discussants are Drs. Herbert Conway, Emmanuel B. B. Kaplan, Leo Mayer, and Thomas W. Stevenson Jr., New York; Robert H. Clifford III, Detroit, and Henry H. Kessler, Newark, medical director of the institute. The lecture is open to all physicians. Those desiring to attend should communicate with the registrar at the Kessler Institute for Rehabilitation, Pleasant Valley Way, West Orange: ORange 3-6571.

NEW YORK

Reserved Seats for the Orchestral Meetings.—The Buffalo Philharmonic Orchestra Society has advised the Erie County Medical Society that it will reserve seats near the aisle for physicians and hospital personnel holding season tickets for either Sunday afternoon or Tuesday evening performances. Complete call service has been arranged.

Panel on Coronary Artery Disease.—A panel discussion on coronary artery disease will be a feature of the dinner meeting of the Onondago County Medical Society and the Syracuse Academy of Medicine, Oct. 6, at the veterans hospital in Syracuse. At 8:30 p. m., Drs. Walter F. Bugden and John J. Duggan, Syracuse, will speak on cardiovascular surgery. Reservations for dinner, 6 p. m., may be made by phoning Dr. Arthur N. Curtiss, SYracuse, 3-4000.

New York City

Cerebral Palsy Course.—The Columbia University College of Physicians and Surgeons announces a course in cerebral palsy, Oct. 12-23, designed for physicians and occupational and physical therapists. Information may be obtained from Dr. James E. McCormack, Associate Dean, Graduate Studies, College of Physicians and Surgeons, 630 W. 168th St., New York 32.

Medicolegal Lectures.—At a meeting of the clinical society of the New York Polyclinic Medical School and Hospital (345 W. 50th St.), Oct. 5, 8:30 p. m., Dr. Thomas A. Gonzales, chief medical examiner, will present "Medicolegal Investigations and Their Relation to Hospital Practice," and Dr. Alexander S. Wiener, serologist to the office of the chief medical examiner, will talk on "Medicolegal Aspects of Blood Tests." Discussion will be by Dr. Dominick J. Di Maio, director of the department of pathology and bacteriology, New York Polyclinic Medical School and Hospital. Members of the medical profession are cordially invited.

University News.—Dr. J. A. Werner Hetrick, president, New York Medical College, Flower and Fifth Avenue Hospitals, has announced the following appointments to the full-time faculty of the New York Medical College for the current academic year: Dr. Alvin M. Donnenfeld, assistant instructor in obstetrics-gynecology; Dr. Stanley R. Opler, assistant professor of pathology, and Drs. Thomas J. Hartnett and Joseph A. Preston, instructors in pathology; Dr. Irwin P. Train, associate professor of surgery; and Drs. Edward M. Miller, Martin E. Silverstein, and Bernard J. Wattiker, instructors in surgery. Dr. Edward J. Nightingale has been appointed student health officer and associate and assistant physician in the department of medicine.

OHIO

Narcotic Violation.—Dr. Walter C. Scheidt, Van Wert, pleaded *nolo contendere* in the U. S. District Court at Cleveland to a charge of violating the federal narcotic law, and on June 30, received a probationary sentence for a period of 18 months.

Cardiac Research.—The Central Ohio Heart Association, 30 E. Broad St., Columbus, has allocated $44,821.55 for research in the causes and treatment of heart disease and $11,800 for fellowships in cardiology. Work on these projects will be conducted at Ohio State University, University Hospital Heart Station, Ohio State Tuberculosis Hospital, and Children's Hospital, Columbus, and at Marion City Hospital and Frederick C. Smith Clinic, Marion.

PENNSYLVANIA

Cancer Program.—The ninth annual meeting and training school of the Pennsylvania division, American Cancer Society, which will be held at the Bedford Springs Hotel in Bedford, Oct. 9-11, offers the following program on Saturday morning:

Diagnosis and Management of Tumors of the Liver, George T. Pack, New York.
Modern Radical Radiotherapy of Cancer of the Cervix, Gilbert H. Fletcher, Houston, Texas.
End Results of Plastic Procedures in Tumors, S. Milton Dupertuis, Pittsburgh.

SOUTH DAKOTA

Medical Licensure.—The South Dakota Board of Medical Examiners has announced passage of legislation creating an annual registration fee of $2 for licenses in that state, effective Jan. 1, 1954. Physicians licensed in South Dakota who wish to maintain that license by payment of the registration fee should contact the South Dakota Board of Medical Examiners, 300 First National Bank Building, Sioux Falls.

TENNESSEE

Dr. Whitacre Goes to Nashville.—Dr. Frank E. Whitacre, chief of the division of obstetrics and gynecology at the University of Tennessee College of Medicine, Memphis, since July 1, 1945, has resigned in order to accept a similar position at the Vanderbilt University School of Medicine in Nashville. Dr. Whitacre served as house officer, instructor, and assistant professor at the University of Chicago from 1930 to 1938. He later joined the staff of the Rockefeller Foundation's medical college in Peiping, China, as professor of obstetrics and gynecology and head of the department and spent two years in a concentration camp in Manila after the Japanese invasion.

Postgraduate Courses.—The postgraduate department of the University of Tennessee Medical Units, Memphis, offers the following postgraduate courses: (1) Oct. 21-23, obstetrics and gynecology (John Gaston Hospital, teaching facility of the college of medicine), under the direction of the division of obstetrics and gynecology; (2) Nov. 4-6, pediatrics (Le Bonheur Children's Hospital), under direction of Dr. F. Thomas Mitchell, professor of pediatrics of the university and chief-of-staff at the hospital; (3) Nov. 18-20, cardiovascular diseases (Institute of Pathology), under direction of the division of medicine of the university. All courses will be limited to 20 physicians. Information may be obtained from the postgraduate department of the university, 4 S. Dunlap, Memphis.

WASHINGTON

Sickness Survey.—The Washington State Medical Association has announced results of its first sickness survey, held Jan. 20, and cosponsored by the University of Washington medical department, Seattle. Diseases of the respiratory system accounted for 17.4% of all visits by physicians; 17.5% of the visits (the largest group numerically) were not specifically related to sickness but were for prenatal and postnatal care, physical examinations, immunizations, etc. The third ranking cause for visits was fractures, sprains, and other externally caused damage to the locomotor system. The state association plans to repeat the survey four times during the year to allow for seasonal variation.

Dr. Wangensteen to Give the Strauss Lecture.—The department of surgery of the University of Washington School of Medicine, Seattle, will sponsor the annual Alfred A. Strauss lecture, Oct. 30, 8:15 p. m., in the Health Sciences Building, University of Washington campus. Dr. Owen H. Wangensteen, professor of surgery, University of Minnesota School of Medicine, Minneapolis, will speak on "Esophageal Aspects of the Peptic Ulcer Problem." The lecture is open to physicians and all other persons in the field of medicine. Dr. Wangensteen's book, "Intestinal Obstructions," received the Samuel D. Gross prize in 1935. The Seattle Surgical Society will give a dinner at the Ranier Club in honor of Dr. Wangensteen before the lecture.

WISCONSIN

Dr. Dailey Day.—The Elcho Community recently honored Dr. Paul J. Dailey on his 65th birthday with a parade, a picnic, a baseball game between the Elcho Cardinals and "Dr. Dailey's babies," and a dinner at the Muskie Inn Hotel. Dr. Dailey has practiced in Elcho for 40 years, has served for 27 years as president of the school board, and has been president of the Elcho State Bank since 1938. He is the town's health officer. His son, Dr. Dee W. Dailey, joined him in practice in 1946.

Course in Cardiology.—The University of Wisconsin Medical School, Madison, announces that a postgraduate course, entitled "Cardiologic Principles in General Practice," will be given Oct. 20-22, at Wisconsin General Hospital, Madison, under the direction of Dr. Herman H. Shapiro, associate professor of clinical medicine. Small group instruction in the reading of electrocardiograms, orthodiagrams, and in cardiologic diagnosis will be included. Symposiums will be held Tuesday, 2:30 p. m., on diagnosis and treatment of congenital heart disease and Thursday, 3:30 p. m., on diagnosis and treatment of uremia. The course will be limited to 20 registrants. Fee is $20, $5 of which must be sent with application to Dr. Robert C. Parkin, University of Wisconsin Medical School, 418 N. Randall Ave., Madison 6.

Dr. Miale Goes to Florida.—Dr. John B. Miale, director of laboratories for St. Joseph's Hospital, Marshfield, since 1946, has been appointed professor of clinical pathology at the University of Miami School of Medicine, Coral Gables, Fla., and will also serve as clinical pathologist at Jackson Memorial Hospital (University Hospital) in Miami, Fla. Dr. Miale has been affiliated with Cornell University Medical College and Brady Urological Institute, New York Hospital, New York; University of North Carolina School of Medicine in Chapel Hill; Strong Memorial-Rochester Municipal Hospitals, Rochester, N. Y.; and Watts Hospital, Durham, N. C. In 1951 he received the annual Sheard-Sanford award of $5,000 from the American Society of Clinical Pathologists for a paper entitled "The Role of Coagulase—Globulin in Normal and Abnormal Coagulation."

GENERAL

Isotope Catalog.—A new catalog of isotopes, both radioactive and stable, produced by Oak Ridge (Tenn.) National Laboratory is now available. The catalog replaces an edition published by the Atomic Energy Commission in March, 1951. More than 100 radioactive and 175 stable isotopes are listed in the new catalog, together with prices and descriptive material. The catalog, at $1 per copy, or information about ORNL-produced radioisotopes may be obtained by writing to Carbide and Carbon Chemicals Company, Oak Ridge National Laboratory, Radioisotope Sales Department, Post Office Box P, Oak Ridge, Tenn.

Award for Research on Infertility.—The American Society for the Study of Sterility announces the 1954 contest for the most outstanding contribution to the subject of infertility and sterility. The winner will receive a cash award of $1,000, and the essay will appear on the program of the 1954 meeting of the society. Essays submitted must be received not later than March 1, 1954, and should be accompanied by (1) a separate sheet of paper bearing a short biographical sketch of the author and (2) a photograph. For details address the American Society for the Study of Sterility, % Dr. Herbert H. Thomas, Secretary, 920 S. 19th St., Birmingham, Ala.

Meeting of Plastic Surgeons.—The American Otorhinologic Plastic Surgery Society, Inc., will hold its annual meeting at the Hotel Morrison, Chicago, Oct. 11, under the presidency of Dr. Harry Neivert, New York. The general membership meeting, 5:30 p. m., will be followed by cocktails and dinner, 7 p. m. The scientific program, 8 p. m., will open with the invitational address, "Operation—Face Lift," by Dr. John F. Pick, Chicago. Dr. James B. Brown, St. Louis, will present, by invitation, "Possibilities and Limitations in Plastic Surgery of the Nose," which will be followed by the round-table discussion, "Rhinoplastic Surgical Problems," at which Dr. Brown will be an honorary guest and Dr. Samuel F. Kelley, New York, will serve as moderator.

International Council of Pharmacologists.—At a meeting open to all pharmacologists attending the International Physiological Congress in Montreal, Canada, it was decided that a council of seven members from seven different nations should be established (1) to look after the interests of the pharmacologists in future international congresses, (2) to explore the possibility and desirability of affiliating with the newly formed

International Union of Physiological Sciences, (3) to collect and distribute information about the activities of pharmacological organizations, and (4) to perform such other functions as might seem necessary and advisable. Council members were elected from Italy, England, Belgium, Denmark, Switzerland, Germany, and the United States. Dr. Carl F. Schmidt, Philadelphia, was named secretary of the group, which adopted the name International Council of Pharmacologists.

Pathologists' Meeting in Chicago.—The annual meeting of the College of American Pathologists will be held at the Drake Hotel, Chicago, Oct. 12-13. Dr. Robert A. Moore, St. Louis, will serve as moderator for the panel discussion, "Methods and Policies of Teaching Pathology to Undergraduate Students," Monday, 10:15 a. m. Dr. Israel Davidsohn, Chicago, will be moderator for the panel discussion, "Training of Residents in Clinical Pathology," 3-5 p. m. This presentation will be followed by a fellowship hour, 5 p. m. Tuesday will be devoted to a "Symposium on Blood Bank Methodology," for which Dr. Donald H. Kaump, Detroit, will serve as moderator. Question and answer period panels will be held at 11:10 a. m. and 3:35 p. m. A fellowship hour in the grand ballroom, 6:30 p. m., will precede the banquet in the Gold Coast room.

Urologists Meet in Cincinnati.—The annual meeting of the North Central Section, American Urological Association, will be held in Cincinnati, Oct. 8-10. Honorary guest speaker will be Dr. George F. Cahill, New York, who will discuss "Adrenal Tumors." The following basic science lectures, by invitation, will be delivered: "The Use of Radioactive Isotopes in Medicine" by Otto Glasser, Ph.D., Cleveland; "Electromyography in the Study of the Urinary Bladder" by Edward L. Corey, Ph.D., Charlottesville, Va.; and "Basic Endocrinology of Man, Testicular Deficiency" by Dr. Alexander Albert, Rochester, Minn. A panel discussion, entitled "Newer Diagnostic Methods in Urology," by invitation, will be moderated by Dr. James C. Sargent, Milwaukee, with Drs. Edgar A. Webb, Minneapolis, Arthur T. Evans, Cincinnati, James W. Merricks, Chicago, and Eugene F. Poutasse, Cleveland, as collaborators.

Grants for Cancer Research.—Applications for grants for scholars in cancer research are being accepted by the Committee on Growth of the National Research Council, acting for the American Cancer Society. These awards are designed to bridge the gap between the completion of fellowship training and the period when the young scientist has thoroughly demonstrated his competence as an independent investigator. A grant of $18,000, payable over three years, will be made to each scholar's institution as a contribution toward his support, his research, or both. These grants are not restricted to the support of persons who have held American Cancer Society fellowships. Applications should be submitted by institutions on behalf of a candidate before Jan. 1, 1954. Information may be obtained from the Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Ave., N.W., Washington 25, D. C.

Association of American Physicians and Surgeons.—The annual meeting of the Association of American Physicians and Surgeons will be held at the LaSalle Hotel, Chicago, Oct. 8-10. An address of welcome will be delivered by Dr. Walter C. Bornemeier, president, Chicago Medical Society. On Friday, 10:25 a. m., Dr. Lewis A. Alesen, Los Angeles, immediate past president of the California Medical Association, will have as his topic "Is the Trend Reversed?" The Hon. John W. Bricker, U. S. Senator from Ohio, will speak at the banquet Friday, 7 p. m. Other guest speakers include the Honorable Carl T. Curtis, U. S. Representative from Nebraska, the Honorable Ralph W. Gwinn, U. S. Representative from New York, Mr. Kenneth McFarland, Topeka, Kan., educational consultant to General Motors, and Mr. Arthur L. Conrad, Chicago, president, the Heritage Foundation. Tickets for the president's luncheon ($3.50) may be obtained at the registration desk before Thursday noon and reservations for the banquet ($6.50) before 10 a. m. Friday.

Gastroenterologists Meet in Los Angeles.—The annual convention of the National Gastroenterological Association will be held at the Biltmore Hotel, Los Angeles, Oct. 12-14 under the presidency of Dr. Felix Cunha, San Francisco. Dr. Cunha will preside over the first session, Monday morning, which will be devoted to a symposium on cirrhosis of the liver. Tuesday, 9 a. m., Dr. Lynn A. Ferguson, Grand Rapids, Mich., will serve as moderator for a panel discussion on diagnosis and management of disease of the large bowel, and Tuesday afternoon a panel discussion on peptic ulcer will be presented by three invited speakers, Drs. Stephen J. Stempien, Beverly Hills, Calif., Joseph A. Weinberg, Long Beach, Calif., and Garnett Cheney, San Francisco. The sessions will close with a panel discussion Wednesday, 4:25 p. m., on latest developments in cancer of the gastrointestinal tract, which will be moderated by Dr. William C. Boeck, Los Angeles, by invitation. The president's annual reception will be held Monday, 7:30 p. m., under the sponsorship of Winthrop-Stearns, Inc. Admission is by card only, to be obtained at the convocation ceremony, Monday, 6 p. m. The annual banquet is scheduled for Tuesday, 7 p. m. A course in postgraduate gastroenterology will be held Oct. 15-17.

Professional Color Television Broadcasters.—The American Cancer Society, in conjunction with the Columbia Broadcasting System TV network, will produce during 1953-1954 a series of 30 closed-circuit one-hour color television programs for physicians in general practice. The series will be viewed by practitioners in Boston, Philadelphia, Pittsburgh, Detroit, Toledo, and New York, with the possibility that other cities will be added as the series progresses. All programs will originate in New York, from the Columbia-Presbyterian Medical Center and from the Memorial Center for Cancer and Allied Diseases. The tentative starting date for the series is Oct. 21, 5-6 p. m., from a studio in Frances Delafield Hospital at Columbia. Programs will be broadcast on alternate Wednesdays up to Dec. 2, after which they will be presented weekly. Each program will be viewed at the receiving end on the new giant color television projection screen, demonstrated publicly for the first time at the recent A. M. A. meeting in New York. In the New York area, the receiver will be located at the New York Academy of Medicine (Hosack Hall). It is estimated that about 3,000 physicians will view the programs as they are telecast. The programs will be color kinescoped, and the kinescopes will ultimately be made available to local medical societies through regional and state offices of the American Cancer Society.

Trudeau-Saranac Consolidation.—The board of trustees of Trudeau Sanatorium, Trudeau, N. Y., recently voted to merge the activities of the Trudeau Sanatorium (the parent corporate body), the Edward L. Trudeau Foundation (a fund established to assist in carrying out the research program of the entire Trudeau organization) and the Saranac Laboratory (one of the research laboratories of the Trudeau organization, which will continue to function under that name), under one administrative organization, with Dr. Gordon M. Meade, formerly medical director of Trudeau Sanatorium, as executive director. This change was made in the interest of uniformity of objectives and increased efficiency of operation. Word of the reorganization has led to erroneous reports that the work of the Saranac Laboratory and other Trudeau laboratories in the field of pulmonary diseases of industrial origin would be discontinued. The board of trustees states that it not only intends to continue research and teaching in the fields of tuberculosis and pulmonary diseases of industrial origin but hopes to expand the work in the latter field. Pending appointment of a successor to Dr. Arthur J. Vorwald, director of the Saranac Laboratory who resigned July 1, work of the laboratory continues under the supervision of Dr. Philip C. Pratt.

A pamphlet, entitled "Answers to Questions from Physicians About Trudeau Sanatorium," was recently prepared to bring physicians up-to-date on the sanatorium, which will celebrate its 70th anniversary next year. Copies of the pamphlet may be had on request to Dr. Roger S. Mitchell, Clinical Director, Trudeau Sanatorium, Trudeau, N. Y.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

	Sept. 19, 1953

Anesthesiologists Meet in Seattle.—The American Society of Anesthesiologists will hold its annual meeting at the Olympic Hotel, Seattle, Oct. 5-9, under the presidency of Dr. Ralph T. Knight, Minneapolis. Dr. John S. Lundy, Rochester, Minn., will serve as moderator at a panel discussion entitled "What Part Can the Anesthesiologist Play in Civil Defense," which will be presented at a 12:30 p. m. luncheon meeting Thursday in the Georgian Room. Participants include Drs. Jesse Allen and Frank L. Cole, San Francisco, Dr. Joel W. Baker, Dr. Quin B. DeMarsh, Dr. Frank J. Leibly, Dr. Frederic C. Moll, and Rear Adm. James R. Fulton (MC) USN, Seattle, Vice Adm. Daniel E. Barbey, USN (Ret.), Dr. John A. Kahl, Seattle, and Dr. Melvin A. Casberg, Washington, D. C. At the Friday luncheon in the Georgian Room Dr. Robert W. Virtue, Denver, will be moderator for a panel discussion on circulatory problems associated with anesthesia. Participants will be Drs. Frederick H. Van Bergen, Minneapolis, Benjamin E. Etsten Boston, Fiorindo A. Simeone, Cleveland, and Earl H. Wood, Rochester, Minn. In addition to these presentations 46 papers will be read. On Oct. 5-6, 78 refresher courses will be conducted on the mezzanine floor. On Wednesday evening will be the first showing, 6 p. m., in the Olympic Bowl, of the motion picture "Intravenous Anesthesia with Barbiturates," produced through the cooperation of the American Society of Anesthesiologists and the American College of Surgeons and sponsored by Abbott Laboratories. Members, wives, and guests are invited. Thursday there will be a dinner dance in the Georgian Room, when the distinguished service award will be presented to Dr. Henry S. Ruth, Haverford, Pa. The guest speaker, Dr. Enrico Ciocatto, professor of anesthesiology, University of Turin, Italy, who will be introduced by Dr. John J. Bonica, Tacoma, Wash., will speak on "Our Method of Selective Analgesia Block for the Therapy of Intractable Pains." Dr. Ciocatto will also conduct two refresher courses.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.
1954 Annual Meeting, San Francisco, June 21-25.
1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Meeting, Atlantic City, N. J., June 6-10.
1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5.9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9. Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15. Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Otorhinologic Society for Plastic Surgery, Morrison Hotel, Chicago, Oct. 11. Dr. Louis J. Feit, 66 Park Ave., New York, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association of State and Territorial Health Offcers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P. Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Constantinian Society, Battery Park Hotel, Asheville, N. C., Oct. 18-21. Dr. C. F. Shook, Medical Director, Owens-Illinois Glass Company, Toledo 1, Ohio, Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14 Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington 6, Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Indiana State Medical Association, French Lick, Oct. 19-21. Mr. James A. Waggener, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave., Madison 5, Wisconsin, Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

Midwestern Section of American Federation for Clinical Research, Congress Hotel, Chicago, Oct. 29. Dr. Robert J. Glaser, 600 S. Kingshighway Blvd., St. Louis 10, Secretary.

National Association for Mental Health, New York, Nov. 17-19. Dr. George S. Stevenson, 1790 Broadway, New York 19, Medical Director.

National Gastroenterological Association, Hotel Biltmore, Los Angeles, Oct. 12-17. Dr. A. Xerxes Rossien, 1819 Broadway, New York 23, Secretary.

National Proctologic Association, Congress Hotel, Chicago, Oct. 15-17. Dr. George E. Mueller, 59 East Madison St., Chicago 2, Secretary.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov. 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

New England Obstetrical and Gynecological Society, Hotel Somerset, Boston, Oct. 28. Dr. Carmi R. Alden, 270 Commonwealth Ave., Boston, Secretary.

New Hampshire Medical Society, Equinox House, Manchester, Vt., Oct. 4-6. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Oct. 26-29. Miss Alma F. O'Donnell, 512 Medical Arts Bldg., Oklahoma City 2, Executive Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 26-30. Miss Irene Rau, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Oregon State Medical Society, Heathman Hotel, Portland, Oct. 14-17. Dr. Charles E. Littlehales, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Regional Meetings, American College of Physicians:

- Western New York, Syracuse, Oct. 9. Dr. E. C. Reifenstein, 109 South Warren St., Syracuse 2, Governor.
- Ohio, Dayton, Oct. 9. Dr. Charles A. Doan, Ohio State University College of Medicine, Columbus 10, Governor.
- Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr. Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.
- Montana-Wyoming, Missoula, Mont., Oct. 9-10. Dr. Harold W. Gregg, 127 West Park Street, Butte, Mont., Governor.
- New England—Conn., Maine, Mass., N. H., R. I., Vt.—Hartford, Conn., Oct. 28. Dr. John C. Leonard, 80 Seymour St., Hartford 15, Conn., Chairman.
- New Jersey, Trenton, Nov. 4. Dr. Edward C. Klein Jr., 73 Lincoln Park, Newark 2, Governor.
- Southeastern—Cuba, Alabama, Florida, Georgia, South Carolina—St. Simons, Sea Island, Ga., Oct. 16-17. Dr. Carter Smith, 384 Peachtree St. N.E., Atlanta 3, Ga., Chairman.

Regional Meetings, American Rheumatism Association:

- Ohio and Western Pennsylvania, Mayflower Hotel, Akron, Ohio, Nov. 11. Dr. Roger Q. Davis, 1405 Goodyear Blvd., Akron 5, Ohio, Chairman.

Southern Medical Association, Municipal Auditorium, Atlanta, Ga., Oct. 26-29. Mr. C. P. Loranz, 1020 Empire Bldg., Birmingham 3, Ala., Secretary.

Southwestern Medical Association, Pioneer Hotel, Tucson, Ariz., Oct. 29-31. Dr. C. C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

Vermont State Medical Society, Equinox House, Manchester, Oct. 4-6. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Roanoke, Roanoke, Oct. 18-21. Mr. Robert I. Howard, 1105 W. Franklin St., Richmond 20, Executive Secretary.

Western Orthopedic Association, Sun Valley, Idaho, Oct. 5-8. Dr. Forrest L. Flashman, 1301 Spring St., Seattle 4, Secretary.

Wisconsin, State Medical Society of, Hotel Schroeder, Milwaukee, Oct. 5-8. Mr. Charles H. Crownhart, 709 East Gorham St., Madison 3, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Congress of International Anesthesia Research Society, Chateau Frontenac, Quebec, Canada, October 26-29. Dr. A. William Friend, 515 Nome Ave., Akron 20, Ohio, Chairman, Program Committee.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Ophthalmology, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 13-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., Secretary-General.

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of Paediatrics, Havana, Cuba, Oct. 12-17. Prof. Felix Hurtado, 5a Avenue 124, Miramar, Havana, Cuba, President.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Leprosy Congress, Madrid, Spain, Oct. 3-10. Dr. Felix Contreras, Moreto 15, Madrid, Spain, Secretary.

International Office of Documentation of Military Medicine, Rome, Italy, Oct. 14-18. Colonel Medecin Prof. A. Campana, Office of the Ministero della Difesa-Esercito, Rome, Italy, Secretary.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. For information write: Mr. S. Henwood, 120 Broadway, New York 5, N. Y., U. S. A.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Obstetrics and Gynecology, Buenos Aires, Argentina, Oct. 26-31.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, *Feb.* 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Pedro Hernandez Gonzalo, 8 No. 358, Vedado, Havana, Cuba, General Secretary.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

South American Congress of Angiology, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayall, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination*. Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Arizona:* Examination. Phoenix, Oct. 22-23. Endorsement. Phoenix, Oct. 24. Executive Secretary, Mr. Robert Carpenter, 401 Security Bldg., Phoenix.

Arkansas:* *Examination*. Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Reciprocity*. Denver, Oct. 13. Final date for filing application was Sept. 14. *Examination*. Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination*. New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic*. Derby, Nov. 10-11. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

Florida:* *Examination*. Jacksonville, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Hawaii: Honolulu, Jan. 11-14. *Examination*. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: Chicago, Oct. 6-8. Superintendent of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Iowa:* *Examination*. Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination*. Louisville, Dec. 7-9. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination*. Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination*. Lansing, Oct. 14-16. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Minnesota:* Minneapolis, Oct. 20-22. Sec., Dr. E. M. Jones, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity*. Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Missouri: Kansas City, Oct. 22-24. Ex. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: Helena, Oct 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination*. Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* Reno, Oct. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Jersey: *Examination*. Trenton, Oct. 20-23. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Oct. 12-13, Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Sante Fe.

New York: *Examination*. New York, Syracuse, Buffalo and Albany, Oct. 6-9. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

North Carolina: *Reciprocity*. Asheville, Oct. 12. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination*. Grand Forks, Jan. 6-9, 1954. *Reciprocity*. Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination*. Columbus, December. *Reciprocity*. Columbus, Oct. 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Reciprocity*. Portland, Oct. 16-17. Sec., Dr. Wilmot C. Foster, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination*. Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

South Dakota:* *Examination*. Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination and Reciprocity*. Salt Lake City, Nov. 17. Director, Mr. Frank E. Lees, 314 State Capitol, Salt Lake City 1.

Virginia: *Examination*. Richmond, Dec. 3-5. *Reciprocity*. Richmond, Dec. 2. Address: Board of Medical Examiners, 631 First St. S.W., Roanoke.

Virgin Islands: *Examination*. Charlotte Amalie, Nov. 11-12. Sec., Dr. Earle M. Rice, Box 90, St. Thomas.

West Virginia: Charleston, Oct. 19. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Reciprocity*. Madison, October 23. *Examination and Reciprocity*. Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: Cheyenne, Oct. 5. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arkansas: *Examination*. Little Rock, Oct. 6-7. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Connecticut: *Examination*. New Haven, Oct. 10. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

District of Columbia: *Examination*. Washington, Oct. 19-20. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination*. Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Iowa: *Examination*. Des Moines, Oct. 13. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination*. Detroit and Ann Arbor, Oct. 9-10. Sec., Mrs. Ann Baker, 410 W. Allegan St., Lansing.

Minnesota: *Examination*. Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska: *Examination*. Omaha, Oct. 6-7. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada: *Examination*. Reno, Oct. 6. Sec., Dr. Donald G. Cooney, Box 9005, University Station, Reno.

New Mexico: *Examination*. Santa Fe, Oct. 18. Sec., Mrs. Marguerite Cantrell, Box 1592, Santa Fe.

South Dakota: *Examination*. Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination*. Memphis, Sept. 23-24. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination*. Austin, October 16 and 17. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination*. Madison, Sept. 19. Final date for filing application is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Sec., Dr. W. H. [illegible] 21 Ransom St., Ripon.

DEATHS

Moore, John Jay ⊕ Colonel, U. S. Army, retired, San Antonio, Texas; born in Fostoria, Ohio, Nov. 12, 1888; Starling-Ohio Medical College, Columbus, 1912; began his military career in 1917 when he was commissioned a first lieutenant in the regular army; a leading radiologist in the Army, started his work in this field in 1919 and held posts as chief of the x-ray and radium services at Walter Reed Army Hospital, Washington, D. Weber, John Joseph ⊕ Pittsburgh; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1917; affiliated with St. Joseph's Hospital, where he died July 29, aged 61, of cerebral hemorrhage.

Williams, Suel Elsworth, Albuquerque, N. Mex.; Ensworth Medical College, St. Joseph, Mo., 1909; died July 20, aged 73, of cerebral hemorrhage.

Wonderlick, Joseph Anthony, Portland, Ore.; University of Oregon Medical School, Portland, 1923; died July 15, aged 67.

DIED WHILE IN MILITARY SERVICE

Brown, Clarence Raymond ⊕ Lieutenant Colonel, U. S. Army, Tupelo, Miss.; born in Tupelo, Miss., March 27, 1912; University of Tennessee College of Memphis, Tenn., 1937; interned at the John Gaston Hospital in Memphis, Tenn.; served a residency at the Walter Reed General Hospital in Washington, D. C., and the Oliver General Hospital in Augusta, Ga.; entered the medical corps of the U. S. Army as a first lieutenant in 1941; became a lieutenant colonel in 1951; served in Europe during World War II; chief, orthopedic section, Percy Jones Army Hospital in Battle Creek, Mich., where he died July 5, aged 41, of coronary occlusion.

Norris, Joseph Esten, Washington, D. C.; born in Washington, D. C., Dec. 5, 1925; University of Chicago School of Medicine, 1949; lieutenant, medical corps, U. S. Naval Reserve; certified by the National Board of Medical Examiners; a naval internship began at the Naval Hospital in Long Beach, Calif., and was completed at the Naval Hospital in San Diego, Calif.; served as medical officer aboard the U. S. S. Burton Island, with the Second Medical Battalion, Second Marine Division, and reported to the Naval Station, Treasure Island, San Francisco, April 25, 1952, where he was serving at the time of his death in the Naval Hospital, Oakland, Calif., June 12, aged 27.

GOVERNMENT SERVICES

NAVY

Medical and Dental Military Symposium.—The Third Medical and Dental Military Symposium will be held at the U. S. Naval Hospital, Chelsea, Mass., Oct. 12-14. Civilian physicians, dentists, nurses, students, military personnel, and any interested members of the allied professions are cordially invited. Among numerous subjects to be discussed will be treatment of anterior poliomyelitis, role of gamma globulin in anterior poliomyelitis, localization of brain tumors by use of radioactive arsenic, dermatological problems in the service, angiocardiography, peritoneal lavage and the artificial kidney, tumors and malignancies of the oral cavity, advances in inhalation therapy, and psychological and physiological relationships in asthma. In addition to service officers, the speakers have been selected largely from the faculties of medical schools and staffs of prominent hospitals in the area. There will be also sections on nursing and hospital administration. Naval reserve officers not on inactive status may obtain one retirement point credit for each day of attendance. Army and Air Force personnel should make arrangements for point credit with their own services. The wearing of uniform by service personnel other than staff is optional.

Training Courses for Naval Reserve Personnel.—Four training courses for male medical department personnel of the Naval Reserve are scheduled to convene during October, November, and December, 1953. The courses are as follows. 1. Insect and Rodent Control: A class is scheduled to convene at the Naval Air Station, Jacksonville, Fla., on the first and third Wednesday of each month. Quotas have been assigned the 1st, 3rd, 4th, 5th, 6th, 8th, and 9th naval districts. 2. Malariology and Insect Control: The Naval Air Station, Alameda, Calif., has scheduled a course in malariology and insect control for Naval Reservists residing in the 11th, 12th, and 13th naval districts. Information may be obtained from the Commanding Officer, Naval Air Station, Alameda, Calif. 3. Amphibious Medicine: The Naval Amphibious Base, Little Creek, Va., has scheduled a course in amphibious medicine to convene on Oct. 5, 1953. The 1st, 3rd, 4th, 6th, 8th, and 9th naval districts have been assigned quotas for this course. 4. Field Medicine: A course in field medicine is scheduled to be conducted at the Marine Corps Base, Camp Pendleton, California, on Oct. 12, 1953, for reserve personnel of the 11th, 12th, and 13th naval districts.

Eligible personnel desiring to attend these courses in a pay status should submit requests to the commandant of their home naval district at the earliest practicable date. Participation in these courses will not increase the possibility of orders to extended active duty.

Course of Instruction.—A course of instruction in medico-military matters will be conducted at the Naval Medical School, Bethesda, Md., Oct. 12-24, 1953. Reserve Medical, Dental, Medical Service, Nurse, and Hospital Corps officers of the 1st, 3rd, 4th, 5th, 6th, 8th, and 9th naval districts, and the Potomac River Naval Command are eligible to attend. During the first week, the medical department of the Navy, the Navy's medical reserve program, and recent advances in military medicine and surgery, including aviation, submarine, and field medicine, will be discussed. Problems confronting medical and dental officers in chemical, bacterial, and radiological warfare, and recommended defensive techniques, will be discussed during the second week.

Reserve medical department officers desiring to attend should submit requests for 14 days' active training duty to their respective commandants at the earliest practicable date. Acceptance of orders to attend this course will not increase the possibility of call to extended active duty.

DEPARTMENT OF DEFENSE

New Institute of Pathology.—The cornerstone for the new Armed Forces Institute of Pathology building will be laid on Oct. 20 at 10 a. m. at the Walter Reed Army Medical Center. Brig. Gen. Elbert DeCoursey, MC, director of the Institute, will preside at the ceremony, and Dr. Melvin A. Casberg, Assistant Secretary of Defense (Health and Medicine) will be the principal speaker. Completion of the building is expected by late spring, 1954, and construction progress, to date, has been on schedule. The building, which will have five stories above ground and three below, is one of the first institutions in Washington designed for resistance to an A-bomb attack.

Concrete blast walls reinforced with steel enclose the main portion of the building. Except for an administrative wing, the entire structure will be windowless. High intensity lighting will be installed throughout the building. Facilities have been planned for a variety of new activities including laboratories for investigative work in histochemistry, cytophysics, historadiobiology, histobacteriology, and virus and tissue culture. Plans also call for rooms to house animals, an x-ray suite, and closed-circuit color television for teaching purposes.

Architect's drawing of the new Armed Forces Institute of Pathology now nearing completion.

VETERANS ADMINISTRATION

Physicians Wanted at Kerrville, Texas.—Physicians interested in the care of chest diseases are needed at the VA Hospital at Kerrville, Texas, a 450-bed hospital predominantly for the care of tuberculous veterans, located in the hills about 65 miles north of San Antonio. There is an active and progressive inservice educational program for physicians, with nearly every specialty represented in charge of board men. General practitioners are eligible and will be trained if necessary for such positions. The usual VA benefits and perquisites are available, with salaries dependent on qualifications and experience. Inquiries are also solicited from surgeons and eye, ear, nose, and throat specialists.

Personal.—Dr. Rolland R. Gasser, formerly manager of the Veterans Administration Hospital at Framingham, Mass., was appointed manager of the newly remodeled hospital at West Roxbury, Mass., effective August 30. Dr. Gasser will continue as acting manager of the Framingham hospital until the portion of the hospital retained by the Veterans Administration is returned to the Department of the Army. The West Roxbury hospital, formerly a 304-bed general medical and surgical hospital, was closed a little over a year ago for conversion to a paraplegic center. When it is opened, the West Roxbury hospital will have 150 beds devoted to the treatment and care of paraplegic veterans and 150 beds for general medical and surgical patients.

FOREIGN LETTERS

ITALY

Meeting on Internal Medicine.—The eighth convention of the Society of Internal Medicine of the Tuscany and Emilia regions was held in Bologna recently under the chairmanship of Prof. Antonio Gasbarrini, from the university of that city. Prof. Massimo Michelazzi discussed the morphological bases of abnormal circulation. He explained the morphological characteristics of the small vessels and discussed the importance that these may have in the interpretation of many aspects of abnormal circulation. He described the muscle sphincters, the intimal bundles of muscular tissue, and the small polypoid structures found in the small arteries and veins and discussed the arteriovenous anastomoses and the structure and location of the myoepithelioid cells.

Professor Michelazzi spoke also of the general hemodynamic effect of anastomoses, with special reference to the return circulation, and he discussed briefly, as an example of anastomotic circulation, the circulation of the pregnant uterus. Then he reported on the vascular structures of the lung and pointed out the physiological postulates that lead to recognition of the existence of extensive communications between arteries and veins and between the bronchial and pulmonary arterial system. He explained in detail the pathways of the pulmonary circulation and also the various possibilities for and importance of the short circuits from right to left or from left to right. He emphasized the importance of these anatomic features in explaining some aspects of the hemodynamics of the lung, especially in the emphysematous patient, and he discussed a disease that is known in Italy as arteriovenous angiomatosis with hypoxemia. This is a congenital disease due to vascular dysplasia with a particular pulmonary tropism caused by the complex vascular structure of the organ.

On the basis of his personal experience, Professor Michelazzi proved that in bronchitic patients with emphysema some vascular aspects may resemble very closely those of the arteriovenous disease with hypoxemia and could be explained either by the stresses to which the complex pulmonary circulation is subjected or by possible signs of latent vascular dysplasia. On the basis of structural peculiarities, even some aspects of cyanosis could be explained in emphysematous patients as due to a shunt from right to left, and bronchitis due to stasis, pulmonary infarction, and hemorrhages in patients with arterial hypertension could be explained and proved. Prof. Sergio Lenzi, Prof. Luigi Rosa, and Dr. Bardelli read papers after Professor Michelazzi's report.

Roman Society of Surgery.—At a meeting of the Roman Society of Surgery, Feb. 7, under the chairmanship of Professor Paolucci, Dr. Ronchetti reported on a quick method to determine the erythrocyte sedimentation rate. He determined it in patients with tuberculosis and other diseases simultaneously by the method of Westergren and by a quick method by which the reading can be taken after 40 to 60 minutes. The results, which were almost the same with the two methods, suggested the possibility of using the quick method advantageously in the laboratory.

Drs. Parentela and Lucifero spoke of the possibility of a quick treatment of reactions secondary to blood transfusions. They reported their results in 24 patients in whom transfusion or perfusion of fresh whole blood, of a homologous type, was followed by reactions. The reactions disappeared almost entirely a short time after intravenous administration of about 10 cc. of a 25% solution of nikethamide (Coramine).

Dr. Natellis explained a technique for the lyophilization of long arterial segments and demonstrated how he prepared and preserved a 12 cm. segment of aorta. Professor Oselladoro, from Milan, reported on mediastinal goiters and clarified some concepts on the subject. According to him, the term posterior mediastinal goiter that is commonly used is not exact; a definition that would indicate the real location and the true correlations of this pathological entity would be "lateral mediastinal goiter" or better yet "laterovisceral mediastinal goiter." Contrary to modern opinion, the so-called posterior mediastinal goiter is not uncommon. The relations of this goiter to the large vessels of the base of the neck differ fundamentally from those of the anterior mediastinal goiter; the difference is considered with respect to the tracheo-esophageal axis according to which the anterior goiter is previsceral whereas the posterior goiter is lateroviscerał.

The pathogenesis of posterior mediastinal goiter is related not only to its origin in the thyroid gland but also to other circumstances that differ from those presented by previous workers. Its symptoms are always milder than those of an anterior goiter, and they are pulmonary rather than mediastinal. The transpleural approach is the method of choice in removing a posterior goiter. In some cases it is possible and therefore useful to use the cervical approach, whereas in others it is necessary to use both approaches.

Professor Paolucci, a clinical surgeon from the University of Rome, congratulated Professor Oselladoro for his report and for the fact that he reported his personal experience. He said that he agrees with most of his ideas and then gave his report on retrosternal goiters. He operated on 25 patients with this type of goiter and had no mortality.

Center for the Study of Epilepsy.—A center for the study of epilepsy began to function in Bologna on May 1. It was established on the basis of agreements reached between the Cavina Neurosurgical Institute, the Ospedale Maggiore of the city, and the city council of Bologna. Professor Miletti, director of the Cavina Institute, explained the tasks of the center, which are to study epileptics that do not benefit from medical therapy and to ascertain whether better results may be obtained with surgical treatment.

Recent reports by the Cavina Institute have confirmed with statistical data that Jacksonian epilepsy occurring in an adult in good health is in most cases due to a cerebral tumor. To relieve the convulsions of these patients with palliative drugs is a grave mistake, since the diagnosis is delayed until other signs, such as a papilla due to stasis, pareses or paralyses and symptoms of intracranial hypertension, appear. These are all symptoms that jeopardize the results of a neurosurgical intervention.

Less often but not uncommonly generalized epilepsy is also a sign of a cerebral tumor, especially if it appears in young persons or in adults in good health. Moreover, some convulsions are caused by factors that can be removed surgically, i. e., meningocerebral scars due to trauma or to infantile encephalopathy, localized vascular lesions, such as aneurysms and angiomas, and diffuse vascular lesions, such as thrombosis and thromboangiitis obliterans (Buerger's disease). These are favorably influenced by a resection of the cervical sympathetic nerve and can be diagnosed easily by radiological means and arteriography.

Today the electroencephalogram is the most important investigative method for the study of epilepsy; it is possible with this technique to determine whether there is an epileptogenic focus. After this focus has been delimited by means of the electroencephalogram, at operation the focus is located by means of the electrocorticogram. With this technique the focus is clearly delimited and then removed surgically; the results of this treatment are satisfactory.

The epileptogenic foci are found more frequently in the temporal area; the clinical picture of these patients is characterized by psychomotor phenomena with periods of automatic or abnormal behavior. The center of Bologna has two laboratories of electroencephalography and laboratories for chemical-clinical analyses and radiological investigations.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Some Statistical Data.—According to the recent publications of the National Institute of Statistics, stillborn infants in Italy numbered 26,948 in 1951 and 25,924 in 1952. From 1951 to 1952 the number of stillborn infants has increased slightly in seven Italian regions and 35 provinces, while it has decreased in the other 12 regions and 56 provinces.

Statistics about nervous and mental diseases indicate an increase, with more patients hospitalized in public institutions but with a lower fatality rate and a greater number of persons discharged from the institutions. This indicates the improvements that have been achieved in treatment of these diseases. It must be emphasized that in the years following World War II nervous and mental diseases assumed a prominent place in Italy; the greatest number of institutionalized patients was reached in 1950, with a total of 35,428. Statistics for accidents in industrial fields show significant improvement. During 1950 and 1951, 1,066,290 accidents occurred compared to 1,183,410 cases for 1941 and 1942.

LONDON

Postinoculation Poliomyelitis.—In 1950, Dr. Dennis Geffen (*M. Officer* **84:**29 [July 15] 1950) was one of the first to draw attention to the apparent association between inoculation with combined diphtheria-pertussis vaccine and poliomyelitis. He reported 30 cases in a London borough of poliomyelitis developing in children within a month of immunization, the site of paralysis being the site of injection. With his colleagues, he has now (*Lancet* **2:**1268 [June 27] 1953) recorded a follow-up on 29 of these children two years after the original illness. The remaining child could not be traced but "there is no reason to doubt that he is alive." As a control group 23 children of approximately the same age were selected who had poliomyelitis involving the arms at the same time but had not had recent injections.

The interval between the last injection and the onset of poliomyelitis ranged from 5 to 36 days, but doubt is expressed as to whether some of the longer intervals are accurate. In approximately 82% of cases it was from 5 to 16 days. The view is expressed that "taking into consideration the possibility that some mothers have not sought medical advice until such time as illness is acute or paralysis is present, it is probably fair to say that, if a child shows no sign of illness distinguishable by a medical practitioner within two or three weeks of injection, the period of risk has passed." At the time of the follow-up examination 46 (39.7%) of 116 limbs of the 29 inoculated children were involved, while in the control group 49 (53.3%) of 92 limbs were involved. This difference tends to confirm the authors' "clinical impression that the paralysis of post-inoculation poliomyelitis, though severe, was more limited in extent than in comparable uninoculated cases." The initial paralysis was severe or very severe in 39 limbs of the injected children, and in 27 cases (69.2%) remained so two years later; the comparable figure for the control group was 64%. "It therefore seems that the difference in recovery in limbs affected to a more or less equal extent in the inoculated and control group is not of significance."

The type of vaccine used in these children was combined diphtheria-pertussis prophylactic in 19, alum-precipitated toxoid in 8, and pertussis vaccine alone in 2. It is not known whether it was given subcutaneously or intramuscularly. Doubt is expressed as to whether immunization at an earlier age would prove effective in avoiding postinoculation poliomyelitis. Finally, the view is expressed that "it has not been proved that lay publicity on post-inoculation poliomyelitis is the reason for the recent reduction in the number of children immunised against diphtheria," and the authors "believe that the public is entitled to know the facts of the situation."

Fresh data on this subject are provided by J. Grant (*Brit. M. J.* **2:**66 [July 11] 1953), who records an epidemic of 112 cases of poliomyelitis in northeast England last year. Eight of the affected children had recently been inoculated. Details are also given of four similar cases in 1950 and one in 1948. Among all children from 6 months to 2 years old, there were 4 cases of poliomyelitis among those recently inoculated and 13 among those who had not been recently inoculated. This gave an attack rate of 1 in 112 for the inoculated children and 1 in 204 for the others. Dr. Grant comments, "In spite of the smallness of these numbers, I feel that they are reasonable in assessing the risk of a child developing poliomyelitis as being at least doubled as a result of intramuscular immunisation during an epidemic." In the recently inoculated patients, paralysis affected only the inoculated arm in three patients and the inoculated leg in one; it extended from the inoculated arm of a fifth patient to involve the opposite arm and leg. In two patients paralysis was localized to the ocular muscles and to the right leg respectively, although the injection had been given in the left arm. The eighth case was a nonparalytic one. Only 60 of the 130 patients not recently inoculated had paralysis and this much oftener involved the legs than the arms. In the five patients in whom the paralysis was definitely associated with the site of injection, the interval between the injection and the onset of symptoms was 15, 16, 16, 16, and 58 days respectively. In the other three cases in which there was not this association, the interval was 3, 5, and 46 days. In the 1948 and 1950 cases in which the sites of injection and of paralysis were associated, the interval was 10, 13, 13, and 18 days.

Attention is drawn to the fact that, considering all 13 cases of poliomyelitis following recent inoculation, the injection given intramuscularly in the arm on 10 occasions was followed by severe paralysis limited to the arm in five patients, and by extensive paralysis involving both arms in three; all these eight patients "have or are likely to have some degree of permanent disability." On the other hand, in three patients inoculated in the buttocks or thigh, only one had paralysis of the injected limb and it was transient. In view of these observations, and the increased tendency for involvement of the arm to be associated with respiratory paralysis as well as the greater handicap of a paralyzed arm than a paralyzed leg, it is suggested that the lower limb should always be used for intramuscular injections. The prophylactics used in these cases of postinoculation poliomyelitis were diphtheria alum-precipitated toxoid, pertussis alum-precipitated vaccine, and combined diphtheria toxoid and pertussis vaccine.

Attention is drawn to the fact that throughout the epidemic many injections of other substances were given intramuscularly. In only one case, however, was there a possible association with poliomyelitis, one in which injections of penicillin were given to a 6-month-old infant. An appeal is made to manufacturers to produce antigens that will be satisfactory for subcutaneous use.

National Health Service Anniversary.—On the occasion of the fifth anniversary of the National Health Service (the service was inaugurated on July 5, 1948) the Ministry of Health has issued some statistics covering these five years that, apart from their propaganda value, have a certain amount of general interest. They are shown in the following tabulation:

Hospital Service	
Staffed beds (in all hospitals)	470,000 (increase, 35,000)
Nursing and midwifery staff	Whole-time 142,000 (increase, 27,000) Part-time 27,000 (increase, 10,000)
Inpatients discharged	16,000,000
Attendances in outpatient departments	150,000,000
Patients supplied with hearing aids	305,000
Total donations of blood	3,000,000
General Medical Services	
Patients on physicians' lists	42,000,000
General Dental Services	
Courses of treatment provided	43,000,000
Dentures supplied	10,500,000
Ophthalmic Service	
Sight tests given	25,000,000
Pairs of glasses supplied	28,000,000
Pharmaceutical Service	
Prescriptions dispensed	1,002,000,000
Maternity and Child Welfare Clinics	
Attendances of mothers at ante- and postnatal clinics	8,500,000
Attendances of children at child welfare clinics	49,000,000
Domiciliary Midwifery Service	
Cases attended by midwives	1,000,000
Cases attended by maternity nurses	250,000

Fluoridation of Water.—The United Kingdom Mission, which visited the United States and Canada last year, has now published its report on "The Fluoridation of Domestic Water Supplies in North America as a Means of Controlling Dental Caries" (London, Her Majesty's Stationery Office, 1953).

In the opinion of the members of the mission, "Epidemiological studies in America have demonstrated beyond doubt that among children and adults who have been born and brought up in areas where the drinking water contains fluoride at a level of 1 p.p.m. or more, there is much less dental caries than in areas where the water is free from fluoride." Further, "The evidence is conclusive that among children in fluoridation areas there is a reduction in dental caries to a level comparable with that experienced where fluoride occurs naturally." In addition, they found "no scientific evidence that there is any danger to health from the continued consumption of water containing fluoride in low concentration."

They therefore recommend the adoption of fluoridation of water in England as "a useful means of reducing the incidence of dental caries" subject to certain preliminary steps being taken. One is to assess the required dose of fluoride to be added to water supplies in this country. One factor that will need to be taken into consideration here are the different food habits in our two countries. For instance, the amount of drinking water consumed in England may well be less than in the States. On the other hand, however, much more tea is consumed in England, and available evidence indicates that many teas are rich in fluoride and therefore a concentration of 1 ppm is not unusual in a cup of tea. These preliminary measures having been taken, the next proposed step is the addition of fluoride to the water supplies of some selected communities. A further cautious, but wise, note is struck in the statement that "in spite of the fact that the evidence of harmlessness is so strong as to be almost conclusive, research into the effects on health and disease of the continued use of water containing low levels of fluoride should be encouraged."

MEXICO

Seventeen Cases of Intestinal Atresia.—In 65,700 admissions to the Children's Hospital in Mexico City intestinal atresia was diagnosed in 17 cases. In five other cases with a clinical diagnosis of intestinal atresia the diagnosis could not be confirmed because the patients died and an autopsy was not performed.

In the *Boletin del Hospital Infantil* (10:28 [Feb.] 1953) Drs. Sariñana and Delgado reported a study of the first 17 cases, 12 in boys and 5 in girls. Six were born prematurely and 11 at full term. In two cases there was a past history of infectious hepatitis in the mother between the fifth and seventh month of pregnancy. In the others no history of virus infection during the pregnancy of the mother was found.

The time elapsed before admission to the hospital varied between 6 hours and 12 days, and the mortality was directly related to the lapse of time before treatment was started. The symptoms were those of intestinal occlusion and abdominal distention; the presence of peritoneal symptoms was related to the clinical stage in which the patient was seen.

The types and locations of atresia were as follows: in 1 case in the duodenum in the form of a diaphragm; in 3 cases in the jejunum with complete division of the intestine; in 10 cases in the ileum with 3 of these in the form of a diaphragm and 7 with complete separation of the lumen; in 2 cases in the ascending colon, with 1 membranous obstruction in 1 case and several such membranes in the other. Treatment in the cases with a membranous diaphragm consisted of rupture of the diaphragm through an incision in the bowel wall. In the cases with separation of the lumen, laterolateral enterostomy was performed, and gastroenterostomy in the case with duodenal atresia.

Thirteen of the 17 patients operated on died and 4 recovered, a mortality of 74.48%. The high mortality rate of the disease can be improved by early treatment; peritoneal and respiratory infections make the prognosis less favorable. Prematurity and the coexistence of other congenital anomalies, such as mongolism and circulatory defects, are also causes of the high mortality rate in these patients.

Eosinophilia in Infectious Hepatitis.—Viral hepatitis is a common disease in Mexico, and its incidence in this country seems to be increasing, as it is in other countries. At the Hospital de Enfermedades de la Nutrición, which is a rather small hospital, more than 200 cases have been studied in the last six years. One peculiarity of the disease that was sometimes observed was eosinophilia.

In order to determine the incidence of eosinophilia, as well as other leukocytic changes, the hematological data from 100 cases of viral hepatitis were analyzed by Drs. Báez-Villaseñor, Domínguez, Cárdenas, and Tech. Cuéllar. The clinical diagnosis was proved by the liver function tests in all of the cases; in addition, in 35 the diagnosis was confirmed by liver biopsy. Finally in three cases with a fatal result, postmortem studies were carried out.

The results of this investigation were published in the April-June issue of the *Revista de Investigación Clínica* (5:209, 1953). According to this report, a normal white blood cell count was found in 73% of the cases, leukopenia in 19%, and leukocytosis in only 8%. Absolute lymphocytosis was present in 40% and monocytosis, usually slight, in 13%. Eosinophilia occurred in 24% of the cases. The average percentage of eosinophils was 8.5%. It was, to a certain degree, parallel to the state and course of the liver function, and consequently it was suggested that it may have some value for determining the prognosis and clinical course of the disease.

SWEDEN

Treatment of Tuberculous Meningitis.—At a recent meeting of the pediatric and school hygiene section of the Swedish Medical Society, Dr. L. Silverstolpe reviewed the results of the treatment of 20 patients with tuberculous meningitis (16 men and 4 children between the ages of 3 and 11 years) at the Stockholm Fever Hospital during the period 1947-1952. None of the 20 had been vaccinated with BCG. The average observation period for the 11 who survived was over three years. Of nine patients given pure streptomycin in doses of 28 to 59 mg. per kilogram of body weight by intramuscular injection plus 50 to 100 mg. of the same drug by intralumbar injection, five survived. There were two deaths among the three patients given dihydrostreptomycin in doses of 35 to 60 mg. per kilogram of body weight by intramuscular injection plus pure streptomycin, 50 to 100 mg. by intralumbar injection. Combined treatment with *p*-aminosalicylic acid (PAS), 3 to 30 grains (0.2 to 2.0 gm.) daily by mouth, plus dihydrostreptomycin by intramuscular injection, and pure streptomycin by intralumbar injection was given to four patients, two of whom died. Among the three patients treated with isoniazid as well as the two forms of streptomycin, there were no fatalities, but two of the patients were still under treatment.

Reviewing the side-effects of streptomycin treatment among the 11 survivors, Dr. Silverstolpe pointed out that 8 of them showed loss of a caloric reaction. Among these eight were six adults with impaired equilibrium in the dark. Impairment of hearing was observed in five patients, one of whom was a child, while one adult was totally deaf. The side-effects of dihydrostreptomycin were so much more serious than those of pure streptomycin that the former should not be used in cases of tuberculous meningitis. Dr. Silverstolpe has come to the conclusion that an early diagnosis does much to improve the prognosis, since in the eight patients for whom complete recovery could be claimed treatment was begun within an average of eight days after the first manifestations of the disease. Much can be done to aid diagnosis by conducting an early search for acid-fast rods in direct preparations of suspect material. The most recent cases in this group received treatment with isoniazid, given by mouth in doses of 8 mg. per kilogram of body weight, combined with pure streptomycin, given by intramuscular injection in amounts of 50 mg. per kilogram of body weight, plus 100 mg. given by intralumbar injection when the concentration of streptomycin in the cerebrospinal fluid did not reach the desired therapeutic level with intramuscular injections alone.

THE LEISURE CORNER

THE "SUNDAY" PAINTER

Throughout the ages generations of physicians have been art-minded, finding considerable pleasure in attending art exhibitions, collecting paintings, and joining the ranks of amateur painters. The precise relationship between art and medicine has never been defined to the complete satisfaction of all participants in the two spheres of activity. Apparently something more than the mere quest for an outlet to expend excess energy, to escape from the monotony of medical routine, or to move away temporarily from the disconcerting problems associated with clinical practice is required to explain why so many members of the medical profession have for so long turned to the world of art as an avocation.

Some famous physicians of the past have actually put their artistic talents to practical use; for example, Richard Bright and Thomas Hodgkin, discoverers of diseases named after them, illustrated their own medical books and articles, while Joseph Lister, father of modern antiseptic surgery, made his own drawings to illustrate his surgical publications. Others, such as S. Weir Mitchell, the neurologist, and A. Graeme Mitchell, the pediatrician, exhibited talent as painters. Even the ancient Greek physicians were concerned with art. More than 2,300 years ago Hippocrates made a statement that can still serve as a motto for most art critics. Said he, "Life is short, art long . . . judgment difficult."

Perhaps among no other group of professional persons has the enthusiasm for painting been more highly developed or organized than among American physicians. Today thousands of physicians spend their spare time as "Sunday" painters splashing vivid colors on canvas or discovering the absorbing excitement connected with sculpturing, carving, whittling, and hammering out all sorts of art forms. Indeed, many of them belong to the American Physicians Art Association, an organization that holds an exhibition each year at the annual meeting of the American Medical Association.

Physicians have readily turned to art because, like artists everywhere, most of them have a quick eye, possess manual dexterity, and exhibit a keen and sympathetic interest in their environment and in human beings. Most of them, too, could be classified as academic artists, i. e., realists who paint along conventional lines. Now, however, great numbers of physicians will be found to paint in various styles and with various techniques. Some doctors, for instance, regard themselves as impressionists, others experiment with arbitrary postimpressionist arrangements of light and color, and still others follow the teachings of the abstractionist school. Yet it can be fairly stated that within the artistic soul of every amateur doctor-painter is an intense urge to raise or improve the standard of his work to the highest possible level. As in the case of most professional persons, physicians have a limited amount of time for relaxing with an avocation. The truth of the matter is that, unlike the professional painter, the "Sunday" painter need never apologize for his work, for the amateur can do no wrong!

It should be quickly realized that there is no such creature as a typical, standard-model "Sunday" painter; hence there can be no typical standardized approach to the teaching and guidance of amateur artists. To illustrate, the lot of the isolated amateur doctor-painter who resides in a small rural community can hardly be compared in terms of wealth of opportunity with that of his colleague in a metropolis like New York City. In this world center of art the amateur painter can easily attend important exhibitions and within a matter of days be able to compare his sense of critical values with those expressed by prominent art critics writing for the metropolitan press. Moreover, the amateur doctor-painter who lives in a big city is often able to attend art classes that have a substantial gamut of activity, ranging from the lone studio of a favored teacher to the hustle and bustle of a large art class.

Nonetheless, the dyed-in-the-wool "Sunday" painter actually requires neither studio nor absolute quiet or peace to pursue his hobby. He need not wait for "inspiration" or a "worthy" subject, for, as one French proverb has it, "Appetite comes with eating." Art can be found in the humblest pair of shoes, a chair, an apple, or an old vase full of flowers. Painting requires only enough initiative to start painting and enough humility to see beauty in the simplest blade of grass. Painting provides a form of meditation and, incidentally, great fun, since it satisfies the universal desire for self-expression. It would be a mistake to believe that all artists are born and not made. Many persons have secret yearnings for painting, and there is a vast amount of wasted talent in the world because so few persons have investigated the possibilities that can be found in the world of the "Sunday" painter.

In general, a basic problem confronting the doctor-painter is how to pick his way gingerly through a labyrinth of advice, art sources, arty discussions, and courses of instruction. The crucial problem, of course, is to avoid easy formulas for painting, facile tricks, clichés, and, for that matter, unswerving homage to some magnetic teacher's style of painting. The doctor-painter should learn his own capabilities, unhinge his mind from stereotyped thought, rediscover his own personality, and find a satisfactory way to think, feel, and express his own response to the world about him. Whether he realizes it or not, an amateur painter can always be relatively free from the restrictions imposed by academic influences and attitudes, and he can blaze new trails in the forest of experimentation. At all times, he might bear in mind the sagacious comment of André Gide, the eminent French writer and critic: "Be faithful to that which exists nowhere but in yourself—and thus make yourself indispensible."

Of course, the cultivation of a hobby and a new form of interest that will appeal to a physician cannot be improvised swiftly or undertaken in a single day. According to Winston Churchill who is probably the best-known amateur painter in the world (although President Dwight Eisenhower threatens him as a rival), everyone should have a hobby, and "to be really safe, one ought to have at least two or three." During World War I, at the age of 40, he discovered that painting was an inexpensive pastime that could not only completely absorb a person's mind without exhausting his body but also served as a companion with whom it was possible to walk a great part of life's journey. Painting, he found, provides new mental food and exercise, a heightened sense of observation, and a fresh appreciation of the paintings of the masters. As a spur to travel, he found that painting is unequalled. Every section of the country has a theme all its own, with individual lights, scenes, charm, and spirit. Even if the amateur painter cannot portray the world around him as he sees it, he is at least able to feel it, know it, and admire it forever.

"To have reached the age of forty," asserts Churchill, who has three paintings hanging in the Royal Academy, "without ever handling a brush or fiddling with a pencil, to have regarded with mature eye the painting of pictures of any kind as a mystery, to have stood agape before the chalk of the pavement artist, and then suddenly to find oneself plunged in the middle of a new and intense form of interest and action with paints and palettes and canvases, and not to be discouraged by results, is an astonishing and enriching experience."

The possession of paint and brushes is an enemy to boredom, even for those human beings whom Churchill broadly divides into three classes; namely, those who are worried to death, those who are toiled to death, and those who are bored to death. If anyone who reads these words doubts the pleasures and joys that come to the amateur painter and to the perpetual challenge of art, let him purchase a paint box and several brushes, a canvas and an easel, and have these objects at hand. Then: if within a short period of time his fingers do not itch to open the tubes of color, if he cannot make his own experiments and express himself in his own individual way, and if he cannot find endless and ecstatic enjoyment in the inexplicable mysteries of painting, it is reasonable to expect that he will not be suitably disposed to join the increasing ranks of "Sunday" painters.

CORRESPONDENCE

CARBON DIOXIDE INHALATION

To the Editor:—In addition to other aspects, Dr. Temple Fay discussed basic mechanisms of the therapeutic procedure described in his survey "Twenty Per Cent Carbon Dioxide Inhalation in Muscular Rigidity" (*J. A. M. A.* 152:1623 [Aug. 22] 1953). While frankly conjectural as to precise details, he felt that "whatever effect it has must be secondary to some profound change in cellular function, caused either directly or indirectly by the gas itself."

Although various types of metabolic neurodynamic mechanisms are hypothesized, no mention is made of possible psychogenic factors that may explain the improvement "sustained . . . in certain types of disease for periods exceeding three years, when fortified by the appropriate physical therapeutic measures now available." It is pointed out that the therapeutic procedure is of little value in patients in whom relaxation while asleep does not reveal a decrease or disappearance of certain rigidities and tremors. This prerequisite for carbon dioxide therapy in itself suggests the psychic overlay present in some symptoms while the patient is awake.

There exists a considerable amount of literature concerning psychosomatic relations between qualitative or quantitative aspects of symptom manifestations in organic neurological disease, and psychical influence on these symptoms; for instance, H. Flanders Dunbar (Emotions and Bodily Changes, ed. 2, New York, Columbia University Press, 1938) in discussing such relationships, abstracts representative opinions including F. Mohr's, stating that according to the latter "psychophysical interaction can be seen very clearly in many organic diseases of the nervous system. How often, for example, a locomotor ataxia in tabes or multiple sclerosis is followed by a psychically conditioned anxiety which may come to overshadow the organic component . . . [as an example] it was possible, by explanation and reassurance, to restore the ability to walk to a degree sufficient for the patient's calling, whereas previous exercise therapy of long duration had been unsuccessful. It is evident that in this way the somatic disease process also is influenced favorably."

Dr. Dunbar quotes a passage from G. R. Heyer's discussion of hypnotherapy which further illustrates the point: "Thus the inner condition of the whole patient plays an important role for normal, pathological and therapeutic processes—which should be obvious. Attention must be paid to the elaboration of the disease—this is truest of all for organic nervous diseases. All these patients, be they tortured by pain or crippled in their motions, become gradually worn out, discouraged and desperate. Out of all proportion to the severity of their physical symptoms, these patients give up hope. The physician who is only a diagnostician stands ever ready to alleviate symptoms with drugs, even with morphine in increasing doses, whereas encouragement (not appeal to the 'will'), suggestion, and hypnosis occasionally accomplish apparently miraculous improvement, as, for example, in crises, lancinating pain, incontinence alvi et urinae, motor disturbances. In cases of multiple sclerosis, tabes, etc., one is reminded of the command 'take up your bed and walk' when one is able to make paralyzed patients get up from their 'mattress graves.' . . . a patient suffering from spastic spinal paralysis was unable to eat or to hold himself erect. After a few periods of superficial hypnosis—which had to be repeated from time to time—he was able to comb his hair, change his shirt, eat, write, etc. It is unnecessary to point out what relief even improvements of this sort may be to such patients. . . . postencephalitics belong perhaps among the more dreary pictures of nervous illness. Here suggestive-hypnotic treatment is always successful, so that it is difficult to understand why it is applied so rarely."

The basic value of inhalation therapy would lie in: "if the qualities of consciousness and activity could be retained and at the same time the relaxation present during sleep maintained, many benefits would be obtained through corrective therapy." It is more than likely that patients who are responsive to carbon dioxide would be responsive to systematic psychotherapy, as seems to hold true in instances in which the gas is used by some in the treatment of psychiatric patients. Furthermore, psychotherapy obviates the risk of exposing a patient to very real physical dangers described by Dr. Fay under the heading "Contraindications and Precautions Necessary."

BERYLLIUM POISONING REGISTRY

To the Editor:—A man-made illness of considerable interest has been reported in the medical literature in this country since 1943 under various titles, in general referring to its association with exposure to certain beryllium compounds. As the years go by, more cases appear from a variety of industrial and research operations using beryllium compounds. With funds supplied by the Atomic Energy Commission, it is planned to develop a beryllium case registry at the Massachusetts General Hospital. The purpose of the registry is to facilitate a study of the epidemiology of this disease, an evaluation of the beryllium hazard of incriminated operations, and dissemination of knowledge of the clinical course of beryllium poisoning, especially in relationship to its medical management. The material collected is to be available for study, and from time to time data will be sent to participating physicians summarizing facts that have been established.

This description is being published in the hope that physicians, roentgenologists, and pathologists who have knowledge of cases of beryllium poisoning will participate in making this beryllium case registry complete. We have facilities and funds for prompt handling of any material, such as case records, roentgenograms, and tissue, that is submitted. It is planned to keep cases entered in the registry anonymous. We shall welcome any correspondence.

SHIPMENT OF PERIODICALS AND BOOKS FOR KOREA

To the Editor:—As a result of the recent appeal published in The Journal, May 30, 1953, page 476, the Alameda Medical Depot on August 1 had received 23 major shipments and numerous small shipments of medical books for trans-shipment to Korea and distribution to Korean medical schools. Services that have books, periodicals, equipment, and other items may ship them to the Commanding Officer, Alameda Medical Depot, Alameda, Calif., marked for KORMEDED, where the Department of the Army will assume responsibility for shipment of the material to Korea for distribution to the Korean medical schools in which they will be of greatest use. Donations of books and periodicals should be limited to those published after 1942. Shipments weighing over 100 lb. but less than a carload, should be shipped via freight (L. C. L. rate) collect. Shipments weighing less than 100 lb. may be shipped via railway express collect. To save expense to the donor, donations should be packed sufficiently to withstand shipment to Alameda only. The Alameda Medical Depot will repack all donations for export to insure safe arrival in Korea.

477 First Ave., New York 16.

COUNCIL ON MEDICAL SERVICE

The Council on Medical Service has completed a study of the organization and operation of 198 county medical society grievance committees. The study is being published in booklet form and is available on request. The following paragraphs contain a brief summary of the data presented in the booklet.

COUNTY MEDICAL SOCIETY GRIEVANCE COMMITTEES

The establishment of improved mechanisms by constituent and component medical societies for adjudicating complaints against physicians is an official recommendation of the American Medical Association. In December, 1949, the House of Delegates adopted a resolution urging that all constituent medical associations establish grievance committees to hear complaints from the public. In 1952, the Council on Medical Service issued a report on grievance committees functioning on a state-wide basis. At that time 36 constituent associations had special committees to handle grievances and 4 states were considering the formation of such committees. By January, 1953, all of the 48 states, the District of Columbia, and Hawaii had formal provision for the hearing of complaints from the public. The 198 societies contributing to this study represent 41% of the 479 societies reporting the existence of some type of grievance committee.

Distribution of Grievance Committees

	Total Societies (Estimated)	Societies Reporting Grievance Committees	Societies Replying	% of Total Reporting
Group 1 (0-14 members).....	1,705*	57	15	26
Group 2 (15-49 members)....		163	60	37
Group 3 (50-99 members)....		91	38	42
Group 4 (100-199 members)..	114	74	36	49
Group 5 (200-299 members)..	42	37	14	38
Group 6 (over 300 members)	71	57	35	61
	1,932	479	198	

* Since the exact number of county societies in each size group is not yet available for 1953, estimated figures are used to show the approximate distribution of the various size societies.

Although previous Council reports have been devoted primarily to state-wide committees, they have also pointed out that "progress made toward attaining a nationwide network of state programs to hear public complaints in no way lessens the importance of similar programs by the local medical societies. . . . Since membership in organized medicine originates in the county medical society, disciplinary action must either originate or end there."

Many complaints are settled more quickly and effectively locally, since a county society committee is usually acquainted with the situation and with the parties involved. A local committee lessens the burden of the state committee and possibly of the complainant and the physician, as well. A local committee may also be effective from a public relations standpoint. The public is more likely to see the service in its true perspective as a self-disciplinary measure by the members of the local medical society. They sometimes object when an outside group is required to police the local society.

A grievance committee as considered here refers to any committee, whatever its title, that receives, and assists in the adjustment of, complaints from the public against individual physicians or the medical profession generally.

Most of the local committees prefer the title "Grievance Committee," although some 50 different titles are now being used. Recently there has been much discussion on the possibility of a more appropriate title than "Grievance Committee." After studying this, however, the Council on Medical Service reported the advisability of continuing the use of this title.

The average local grievance committee began operation in 1949 or after. This action on the part of so many was, no doubt, prompted by the resolution of the House of Delegates, urging the formation of such committees. It should be mentioned that the larger societies are more likely to have a long-standing committee of this type, while the smaller society is likely to have begun its committee within the last five years.

MEMBERSHIP

Local grievance committees do not normally have lay membership. The few reporting such membership usually have two lay members, either elected by the society or appointed by the president of the society. Inclusion of laymen in grievance committees is still in the experimental stage but may serve to strengthen community trust in the impartial attitude of the committee by assuring the representation of the patient's viewpoint. Physician membership ranges from 1 to 90 members; however, the average committee in this study has three physicians, usually appointed by the president of the society. The committee chairman is appointed by the president of the society in most cases.

MEETINGS AND JURISDICTION

Grievance committees generally meet on call, whenever the need arises. Some committees have never met, since they have received no complaints. Because of this arrangement, some societies have questioned the worth of maintaining the committee in formal existence. However, the existence of such a committee is an earnest effort on the part of the society to hear any grievances against society members.

The typical grievance committee handles complaints concerning individual society members, any physician in the county, and the society as a whole. The society has no authority over physicians who are not members, but, as the representative of the medical profession, it finds that interest in resolving disputes between patients and these nonmember physicians is worth while. Complaints from any source, on all phases of medical care, are heard by the committee. In answer to the question about committee authority, arbitration or referral of the complaint to the society's disciplinary body are the extent of the average committee's jurisdiction.

Although some societies argue that the existence of a grievance committee invites trouble from "cranks" and psychopaths, the average grievance committee of the smaller societies receives only one complaint, if any, during the year. Obviously, the larger societies have more complaints because they have more physician members and more patients are served. Fees, inadequate service, and general misunderstandings are the commonest sources of complaint. The committee strives to arrive at a decision satisfactory to both patient and physician.

METHODS OF OPERATION

Various methods of receiving complaints are in operation among the various counties responding, but complaints are usually received in written form only. Unless a direct complaint has been received, the typical committee cannot initiate investigations on its own authority. In most cases society members are requested to answer complaints in writing. Most of the committees prefer to avoid formal arbitration and make every attempt to settle the complaint "out of court." The patient is asked to discuss his grievance with his physician before the committee will consider the case. If the complaint does come before the committee, the parties involved are usually questioned separately. The average society has arrangements whereby committee decisions can be appealed by either the physician or the patient. The most popular board of appeal is the state grievance committee.

Committees usually report on cases at the regular society meetings. Although this is considered the average situation, a number of counties do not report on cases handled. Names of physicians involved in cases are usually omitted in reports to the society as a whole. One committee that reported the names in the society bulletin was instructed by the society to keep this information confidential in the future.

Approximately 61% of the committees have no formal liaison with state grievance committees, and 87% make no reports to state committees. More than 50% of the 175 committees reporting in this category do not routinely refer difficult cases to the state committee for settlement.

PUBLIC RELATIONS

"It pays to advertise," and a "well-informed public" are oft-repeated phrases. In the case of grievance committees, however, most of the societies have confined their publicity to an announcement of the committee's formation. In the great majority of the societies, the names of the members of the committee are not announced to the public. Comparatively few societies report that the public was given complete information on how to use the committee. If the grievance committee were to continue publicity, replies indicate that it would choose the newspapers and the radio as the most effective channels. Despite the fact that one society reports that it receives no cooperation from the local newspapers, the typical committee generally does not receive adverse publicity. Failure to publicize the committee is generally the result of an effort to discourage ill-founded and nuisance complaints.

COMMENT

The information presented in this summary has been condensed from a more detailed Council report in order to present a picture of the average local grievance committee, its organization and operation. Local mechanisms are most important in the larger urban and metropolitan areas, since state committees may well serve to cover effectively the small urban and rural areas. It is most important that the committee functions and procedures be clearly defined for satisfactory operation of the program.

Lack of understanding accounts for many of the complaints received. Physicians do not take time to discuss either the services or the charges. Frequently complaints result from the lack of knowledge that medical care includes other costs, as well as the physician's fee. Today, a doctor's every action reflects not upon himself alone but on the entire medical profession. A certain minimum of police work is necessary to protect the profession's good name. The grievance committee is a protective mechanism for both the public and the medical profession and should be regarded as such. Even when few complaints are received, the committee's existence is valuable in demonstrating the medical profession's willingness to discuss problems of medical care with the public. It is one means of explaining the problems that the public does not understand about the practice of medicine, and it also gives the doctor insight into problems of his patients, about which he may have been unaware. The existence of a grievance committee, empowered to investigate the complaint of a dissatisfied patient, serves to improve professional conduct. Furthermore, public confidence in the profession is strengthened.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Taxes: Deductibility of Expenses of Postgraduate Study.—The petitioner claimed a certain expense to be an allowable deduction from his income tax. The Commissioner of Internal Revenue disallowed the deduction, and the tax court upheld the disallowance on the ground that the expenses were nonbusiness ones "because of the educational and personal nature of the object pursued by the petitioner." The petitioner, therefore, appealed to the United States Court of Appeals, Second Circuit. He had been a member of the bar for many years and in 1944 was admitted to practice before the Treasury Department. In 1946 he was in active practice in Binghamton, N. Y., as a member of a firm of lawyers there. The firm engaged in general practice but did considerable work that required at least one member to be skilled in matters pertaining to federal taxation and to maintain such skill by keeping informed as to changes in the tax laws and the significance of pertinent court decisions when made. His partners relied on the petitioner to keep advised on that subject, and he accepted that responsibility. One of the various ways in which he discharged it was by attending, in the above-mentioned year, the Fifth Annual Institute on Federal Taxation, which was conducted in New York City under the sponsorship of the Division of General Education of New York University. In so doing he incurred expenses for tuition, travel, board, and lodging of $305, which he claimed as an allowable deduction under section 23 (a) (1) (A) I.R.C., as ordinary and necessary expenses incurred in carrying on a trade or business. The Institute on Federal Taxation was not conducted for the benefit of those unversed in the subject of federal taxation, and students were warned away. In 1946, it was attended by 408 attorneys, accountants, trust officers, executives of corporations and the like. In 1947, over 1,500 of such persons from many states were in attendance. The course was "designed by its sponsors to provide a place and atmosphere where practitioners could gather trends, thinking and developments in the field of Federal taxation from experts accomplished in that field."

We may start, said the court, by noticing that the petitioner does not rely on the section of the Internal Revenue Code that permits the deduction of certain nontrade or nonbusiness expenses, but rests entirely on his contention that the deduction he took was allowable as an ordinary and necessary expense incurred in the practice of his profession. The expenses were deductible if they were "directly connected with" or "proximately resulted from" the practice of his profession. And if it were usual for lawyers in practice similar to his to incur such expenses they were "ordinary." They were also "necessary" if appropriate and helpful. But this, the court continued, is an instance emphasizing how dim a line is drawn between expenses that are deductible because incurred in trade or business, i. e., because professional, and those that are nondeductible because personal.

In a prior United States Supreme Court case there is a dictum that the cost of acquiring learning is a personal expense. The issue decided in that case, however, said the court, is far removed from the one involved here. There the taxpayer paid debts for which he was not legally liable whose payment enhanced his reputation for personal integrity and consequently the value of the good will of his business, and it was held that these payments were personal expenses. The general reference to the cost of education as a personal expense was made by way of illustrating the point then under decision, and it related to that knowledge obtained for its own sake as an addition to one's cultural background or for possible use in some work that might be started in the future. There was no indication that an exception is not to be made where the information acquired was needed for use in a lawyer's established practice. This situation, the court continued, is closely akin to a decision of the Court of Appeals where the expenses incurred by a teacher in attending a summer school were held deductible. The only difference is in the degree of necessity that prompted the incurrence of the expenses. The teacher could not retain her position unless she complied with the requirements for the renewal of her teaching certificate; and an optional way to do that, and the one she chose, was to take courses in education at a recognized institute of learning. Here the petitioner did not need a renewal of his license to practice, and it may be assumed that he could have continued as a member of his firm whether or not he kept currently informed as to the law of federal taxation. But he was morally bound to keep so informed and did so, in part, by means of his attendance at this session of the institute. It was a way well adapted to fulfill his professional duty to keep sharp the tools he actually used in his going trade or business. It may be that the knowledge he thus gained incidentally increased his fund of learning in general, and, in that sense, the cost of acquiring it may have been a personal expense, but we think that the immediate, over-all professional need to incur the expenses in order to perform his work with due regard to the current status of the law so overshadows the personal aspect that it is the decisive factor. Even if in its cultural aspect knowledge should for tax purposes be considered in the nature of a capital asset, as was suggested, the rather evanescent character of that for which the petitioner spent his money deprives it of the sort of permanency such a concept embraces.

Accordingly the decision of the Commissioner and the tax court was reversed, and the cause was remanded for the allowance of the claimed deduction. *Coughlin v. Commissioner of Internal Revenue, 203 F. (2d) 307.*

MEDICAL LITERATURE ABSTRACTS

Bacillus Anthracis: Sensitivity to Antibiotics.—Special circumstances made available to Roger 29 strains of Bacillus anthracis. Fifteen of the strains had been preserved at 20 C for from 10 to 13 years after their isolation from human infections. The virulence of these strains was established by guinea pig tests. The remaining 14 strains were freshly isolated from human cases of the disease. All of the 29 strains were tested in vitro for susceptibility to seven antibiotics: chlortetracycline (Aureomycin), chloramphenicol, neomycin, penicillin, polymyxin, streptomycin, and oxytetracycline (Terramycin). Uniform sensitivity of all strains to chlortetracycline and oxytetracycline was observed; on the other hand, all were resistant to polymyxin. The greatest variation in sensitivity within these strains was observed with reference to penicillin. The degree of sensitivity of these strains to streptomycin and neomycin was similar, and they may be regarded as moderately sensitive to these two agents. Clinical experience demonstrated that chlortetracycline, chloramphenicol, penicillin, and oxytetracycline are of value in the treatment of cutaneous anthrax, and the laboratory observations of in vitro susceptibility to these antibiotics correlate well with the therapeutic results. It might therefore be predicted on the basis of these laboratory tests that streptomycin and neomycin would prove of value in the treatment of cutaneous anthrax.

Cutaneous Response to Injection of Acetylcholine and Epinephrine in Atopic Dermatitis.—Etiological concepts of atopic dermatitis range from the pure "allergic" to the pure "psychosomatic." A series of physiological studies is being undertaken of the etiological mechanisms involved in the production of this syndrome. When the skin of the normal person is firmly stroked with a pointed (blunt) instrument, there takes place the triple response of Lewis and Grant: (1) red line, (2) flare, and (3) wheal. The "red line" develops in 3 to 15 seconds and is due to dilatation of the capillaries, and is not dependent upon nervous mechanisms. The "flare" (or spreading flush) develops a few seconds after the red line, and is due to an axon-reflex dilatation of the arterioles, and is dependent upon local nervous mechanisms (axon reflex). The "wheal" (or local edema) completely replaces the red line (red reaction), and develops in one to three minutes after injury, is surrounded by the flare, and is due to transudation of fluid from the minute vessels (capillaries) involved previously in the production of the red line (red reaction). Evidence has been presented that a diffusible H substance (or histamine) is responsible for the three reactions. When the skin of the patient with atopic dermatitis is stroked with a pointed instrument, the red line appears in 15 seconds; 5 to 15 seconds later vasoconstriction occurs, producing a blanch that replaces the red line, the well-known white line or "white dermographism." This blanching does not have any whealing component. In studying cutaneous vascular physiology it is important to know what will be the vascular response to adrenergic stimuli (epinephrine) and to cholinergic stimuli (acetylcholine). Observations on 10 patients with atopic dermatitis who received intradermal injection of acetylcholine and epinephrine revealed that the response to epinephrine is the same as that in normal persons, including the production of moderate sweating in the vasoconstrictor zone. The sweat response and axon-reflex response to acetylcholine are normal. However, a marked deviation from normal is evidenced by the "delayed blanch" (vasoconstriction) beyond the injection wheal that occurs between three and five minutes after the intradermal injection. The slowness of onset of the "delayed blanch" and of its spread peripherally, and the lymphatic-like type of spread making pseudopods of vasoconstriction not associated with whealing also suggest that the phenomenon was the result of the direct action of the vasoconstrictor substance on the blood vessels of the skin. Such a vasoconstrictor substance is either (1) acetylcholine itself acting to give a motor response (constrictor) rather than the usual inhibitor response (dilator), or (2) some other vasoconstricting substance which is being released after acetylcholine has been injected. There is no precedent in the literature for the latter supposition, but there is for the former, i. e., acetylcholine can produce a motor (constrictor) response.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

radicular syndromes, dysarthria, epilepsy, and involuntary movements, in few cases was any serious physical disability found on reexamination after several years, and there were no instances of progressive nervous illness, except one of coincidental postencephalitic Parkinsonism. Psychiatric sequelae were common and oftener disabling. The focal cerebral illness may arise from thrombosis in arteries or veins which are the seat of inflammatory change. As regards the prognostic evaluation of these cases, the author says that they are "selected" to the extent that every surviving patient at some stage received a pension for disability resulting from neurological illness following vaccination. It is possible that cases of similar illness in which recovery occurred without sequelae have been omitted. That the present series may be more representative than this qualification would imply is suggested by figures provided by one of the fighting services at risk during this period. Among 1,750,000 persons vaccinated between 1941 and 1950, 10 had postvaccinal encephalomyelitis (an incidence of 1 in 175,000 vaccinations), with 3 deaths. The mortality is identical with that reported in the present series. If one bears in mind the possible omission of milder cases, the mortality rate in the present series is in keeping with that previously reported. Death occurred in 8 of 27 cases.

Wilson's (Hepatolenticular) Disease.—Two siblings of a family in which five of six siblings in 1931 had been discovered by Curran to have Strümpell-Westphal pseudosclerosis, or progressive hepatolenticular degeneration, were again hospitalized in 1952, and presented Sullivan and associates with the opportunity to study again and to review an unusually large family group with this disorder and to observe the natural history of the disease during a 21-year period. Wilson, in his discussion of hepatolenticular degeneration, noted only one family with more members afflicted, a family of 14 in which 6 members had the disease. He reported only two patients who lived more than 20 years after the onset of symptoms. Recent studies have indicated that even the members of the family with no clinical evidence of hepatolenticular degeneration may show some characteristic biochemical dysfunction, notably a nonspecific aminoaciduria. This paper extends the histories first presented by Curran and describes recent studies of the four remaining members of the family. Five of seven children of this family, including a pair of twins, have had progressive hepatolenticular degeneration. The twins exhibit characteristic low serum copper concentration and ceruloplasmin content, but no such abnormality can be demonstrated in the unaffected members of the family.

Hypercholesteremia in Hospital Population.—The serum cholesterol level was studied in 250 men and 250 women (consecutive admissions) at the Mount Sinai Hospital in New York. A specimen of venous blood was withdrawn the morning following admission after the patient had fasted for 12 hours. The Schoenheimer and Sperry method was used. Hypercholesteremia was considered to be present when the cholesterol level exceeded 279 mg. per 100 ml. of serum. On this basis 97 patients (41 men and 56 women) were hypercholesteremic, their average age being 52.8 years and the average cholesterol level 348 mg. per 100 ml. of serum. Diseases which are generally associated with hypercholesteremia were found in 22 of these hypercholesteremic patients and they were therefore excluded from further consideration. Thus 75 patients (32 men and 43 women) had idiopathic hypercholesteremia. An analysis was possible of the families of only 59 of these patients. The study included 97 siblings and 110 children who were essentially healthy persons. Hypercholesteremia was found in 51.5% of the siblings and 29.4% of the children. The study was repeated taking into consideration the persons' age, since other authors have found that serum cholesterol levels vary with age. On this basis hypercholesteremia was found in 12% of the 478 patients, 36.2% of the siblings of the 59 hypercholesteremic patients whose families were studied, and 34% of their children. Of the 478 patients 266 were Jewish. Hypercholesteremia was found more frequently among them than among the non-Jewish patients (21% as against 9%). However, hypercholesteremia was as frequent among the siblings and the children of the Jewish patients as among those of the non-Jewish patients. This seems to indicate that environmental factors (different occupations, housing, diet) are not of decisive importance in determining the presence or absence of hypercholesteremia. It seems to suggest that the disease is primarily genetically determined and that the gene leading to a disturbance of the lipid metabolism that manifest itself as hypercholesteremia occurs more frequently among Jewish than non-Jewish persons.

Natural Course of Syphilitic Aortic Insufficiency.—The course of syphilitic aortic insufficiency was investigated for 20 years in 309 patients from the New York Hospital and 711 from the Johns Hopkins Hospital. A diagnosis of aortic insufficiency thought to be due to syphilis had been made in all of these patients. About 70% of those from the first institution and 85% of those from the second were followed throughout the study period or to the time of their death. The long-term prognosis was good; 43% and 33% of the patients survived 10 years and 30% and 20% survived 15 years at the New York and Johns Hopkins hospitals, respectively. The patients who were free of symptoms at the time of diagnosis had a greater survival than those who already had symptoms; 51% of the first group survived 10 years as against 29% of the second group; 58% of patients who never had symptoms survived 10 years, whereas only 25% of the patients who developed them after the diagnosis survived the same period of time from the day of onset. The patient's age at the time of diagnosis had some effect on the survival period but it was never so pronounced as is often thought. The death rate was slightly increased during the first five years of the disease in patients who were under 40 years of age at the time of diagnosis, but thereafter the prognosis was better in these patients than in those who were older when first seen. About 54% of the patients in this age group survived 5 years, 35% 10 years, and 30% 15 years. On the other hand, 42% of patients who were 60 years of age when first seen survived 5 years, 21% 10 years, and 12% 15 years. The effect of race and sex on the prognosis was hard to evaluate; Negro men, however, had a poorer prognosis than Negro women or whites of both sexes. The effect of the patient's type of work could not be investigated thoroughly, but most of the patients had been compelled to heavy physical exertion because of their economic condition. Congestive heart failure and angina were the complications which were found to be significant in this study. Less than 20% of the patients with failure at the time of diagnosis survived 5 years and less than 6% survived 10 years. Those who remained free of failure showed a very low mortality, 56% surviving 15 years. Of those who remained free of angina 29% survived 10 years as against 17% of those who had this symptom. It was not possible to evaluate the effect of treatment prior to or after the time of diagnosis. A total of 632 patients died, 439 among those seen at the Johns Hopkins Hospital and 139 among those seen at the New York Hospital. About 75% of patients in each group died with symptoms of cardiovascular disease. Autopsy was performed in 219 patients and it proved the presence of syphilitic aortic insufficiency in 84.6% and 81.9% of the Johns Hopkins and the New York hospitals patients, respectively. An additional 11.4% had aortitis without demonstrable insufficiency among the New York Hospital group.

Use of Quinidine in Chronic Auricular Fibrillation.—Regular sinus rhythm can be reestablished and maintained in many patients with chronic auricular fibrillation by the judicious use of quinidine. The degree of success attained depends to a large extent on the cause of the fibrillation. In a group of 34 patients treated by the authors those with arteriosclerotic heart disease and thyroid heart disease showed the best results. Patients were started on 0.2 gm. of quinidine every two hours for six doses; if sinus rhythm was not restored on this dosage, no further quinidine was given until the following day. Each individual dose was then increased by 0.2 gm. daily until conversion occurred or the dose amounted to 0.8 gm. every two hours. No further attempt was made to reestablish sinus rhythm when fibrillation continued after the maximum dosage was reached. The greatest number of conversions were secured with a dosage of 0.4 gm. every two hours. Reactions severe enough to require discontinuance of the drug were observed in six cases. One patient with mitral stenosis of rheumatic origin and recent hemiplegia from embolization died in her sleep the day after conversion had apparently been secured. The risk of embolization or sudden death is not appreciably increased during quinidine therapy, and any risk involved can be lessened by careful observance of the contraindications to the treatment. Preliminary digitalization, if it can be carried out, will afford protection against a very rapid ventricular rate. Conversion was secured in 24 of the 34 patients; follow-up of 22 of these showed 19 living and 3 dead, two from congestive failure and one from an unknown cause. Sixteen of the 19 survivors had maintained sinus rhythm for periods ranging from 18 months to a few weeks in the case of those treated most recently. Auricular fibrillation in itself produces cardiac dilatation and progressive heart failure in patients with otherwise normal hearts; conversion, which carries little risk and is followed by great improvement in the patient's well-being, should therefore be attempted whenever possible.

Five-Year Follow-Up in Miliary and Meningeal Tuberculosis.—Final survival figures for 100 patients with acute disseminated miliary tuberculosis or tuberculous meningitis or both treated with streptomycin in Veterans Administration hospitals during the year beginning in April, 1946, have now been compiled. Follow-up at the end of two years showed 21 survivors; of these, six have since died, leaving 15 survivors in all at the end of five years. Miliary tuberculosis was followed by meningitis in 13 patients, none of whom was alive at the time of the two-year follow-up. All deaths due to the original miliary or meningeal tuberculosis occurred in the first two and one-half years. Classification of the patients alive and well five years after the completion of treatment showed the following percentages according to the type of disease originally present: (1) miliary tuberculosis: alive, 47%, and well, 37%; (2) miliary tuberculosis and tuberculous meningitis combined: alive and well, 4%; and (3) tuberculous meningitis: alive 12%, and well, 7%.

X-Ray Diagnosis of Uterine Disorders.—Hysterosalpingography has not come into general use, because of the complications and fatalities caused by the iodized oils. With the discovery of aqueous radiopaque mediums for use in excretory urography a safe material presented itself for hysterosalpingography. Davids states that at the gynecological service of Mount Sinai Hospital, in New York, over 3,000 hysterosalpingograms have been made with relatively few complications. The patient is placed in a lithotomy position on a table equipped with a Bucky diaphragm. After a preliminary film of the abdomen and the pelvis a bivalve speculum is inserted into the vagina and the cervix is exposed and painted with an antiseptic. The anterior lip of the cervix is grasped with a tenaculum and a sound introduced into the uterine cavity to note its direction and depth. The iodized material is injected into the cervical canal by a syringe attached to an insufflation cannula equipped with a rubber acorn tip. Occlusion of the external cervical os is obtained by pressure with the acorn tip. Opaque material is injected slowly and films are taken after the injection of 1, 2, or 4 cc. of the dye. A film in the oblique position, taken after the last injection, facilitates the demonstration of lesions on the posterior uterine wall which might otherwise escape detection. The method is contraindicated in acute and subacute pelvic inflammatory disease, intrauterine gestation, cervicitis with purulent discharge, and uterine bleeding. The following conditions have been demonstrated by hysterography: endometrial polyps, submucous and intramural fibroids, hyperplastic endometrium, adenomyosis, fundal carcinoma, tuberculous endometritis, congenital anomalies of uterine cervix and fundus, cervical strictures, chronic endocervicitis, and pregnancy and retained secundines. Extravasation of opaque medium into the uterine and pelvic vascular system occurred in 2% of the patients. Since the medium is water soluble, there was no untoward reaction. It is only when large amounts of the opaque medium are employed for outlining the uterine tubes that pain results owing to spill into the peritoneal cavity or owing to distention of the uterus and tubes under pressure. Embolization and granulomas do not occur, since there is rapid absorption of the water-soluble dyes. Allergic phenomena occurred in very rare instances and were easily controlled. Pelvic inflammatory reactions occurred only when a subacute or chronic salpingitis was reactivated.

Testicular Feminization in Male Pseudohermaphrodites.—Morris discusses a clinically recognizable syndrome found in patients who are essentially normal-appearing women, but who have undescended testes in place of ovaries. These patients are actually male pseudohermaphrodites, but the term "pseudohermaphroditism" usually connotes congenital abnormalities of the external genitals resulting in confusion of the sex. The patients under discussion are of a typical feminine appearance with secondary sex characteristics and show female external genitals. Frequently the patients have been married with marital satisfaction, and no complaint except of sterility. Morris presents the histories of two cases, one observed in a Massachusetts hospital and the other in Stockholm, Sweden. He lists the following as the most significant features of such cases: 1. Female habitus, breast development, and other secondary sex characteristics. 2. Scanty or absent axillary or pubic hair in most cases. 3. Female external genitals, with a tendency to underdevelopment of labia, and a blind-ending vagina. 4. Absence of internal genitals except for rudimentary anlage and for gonads which may be located intra-abdominally or along the course of the inguinal canal. 5. Gonads histologically consistent with undescended testes. 6. Urinary excretion studies suggest that such testes produce estrogen and androgen. Elevated urinary gonadotropins have also been found. From the psychosexual aspect these patients are definitely female. As in all intersexes, there seems to be an unusually high incidence of psychosis and suicide, especially when the patient has commenced to suspect that she is abnormal. Owing to the role of these gonads in producing female development, it would seem justifiable to leave them in place until such development has occurred. If seen during puberty it might be worth while providing supplementary estrogen to see if more complete feminization could be obtained such as development of the vulva and production of pubic hair, and to see if the stature and build could be made more typically female by earlier epiphyseal closure. After adolescence surgical removal appears advisable to avoid the very real danger of neoplasia. In addition to adenomas and cysts there were seven malignant tumors in the 82 cases collected.

Bathing Water Quality and Health.—A series of field studies were undertaken to determine the relationship between natural bathing water quality and its effect upon the health of the bather. The aims were to determine what relative increase in illness incidence might be expected from swimming in the cleanest waters and in water containing various degrees of bacterial pollution. Consideration was not given to the less tangible aspects of outdoor swimming, such as fresh air, mental relaxation, moderate amounts of sunshine, physical exercise, etc. The locations were Lake Michigan at Chicago, Ill., the Ohio River at Dayton, Ky., and a nearby swimming pool in the same area; and Long Island Sound at New Rochelle and Mamaroneck, N. Y. The studies demonstrated that an appreciably higher over-all illness incidence may be expected in the swimming group over that in the nonswimming group regardless of the bathing water quality. Eye, ear, nose, and throat ailments may be expected to represent more than half of the over-all illness incidence, gastrointestinal disturbance up to one-fifth, and skin irritations and other illnesses the balance. Specific correlation between illness incidence and bathing in waters of a particular bacterial quality was observed in two instances. This evidence should not be taken as conclusive, however, since a complete analysis of the effect that weather might have had on the result was not possible, but the apparent relation between illness and bacterial quality does provide a warning signal. Despite the relatively low incidence of gastrointestinal disturbance, swimming in river water having a median coliform density of 2,700 per 100 ml. appears to have caused a significant increase in such illnesses among the swimmers. Admitting the difficulties of conducting studies in which nature rather than man controls many of the variables, sufficient evidence is available to indicate that some of the strictest bacterial quality requirements for natural bathing water now existent might be relaxed without significant detrimental effect on the health of the bathers.

Epidemics of Histoplasmosis.—This report is based on 13 epidemic outbreaks of histoplasmosis. Grayston and his coworkers find that with the exception of the generalized variety, histoplasmosis is predominantly a pulmonary infection. The theory that the usual mode of infection is by inhalation gains support from the nature of the disease and from the apparent mode of infection in this series of epidemics. In many of the epidemics it was found that exposure to dust created by agitation of material proved to contain Histoplasma spores resulted, after from one to three weeks, in illness associated with numerous discrete pulmonary infiltrations. A correlation between the number of the lesions and the severity of the illness on the one hand and the length and intensity of the dusty exposure on the other was established both between epidemics and within a given epidemic. The x-ray picture of numerous discrete pulmonary infiltrations would appear to represent numerous primary lesions caused by inhalation of a large number of spores with their deposition in many alveoli. The frequent association with animal excreta is of interest. The excreta probably merely contributed to a good growth condition rather than indicating an animal carrier. The involvement of wood as a vehicle of infection in four of the epidemics further emphasizes its position as possibly important to the growth of Histoplasma in nature. Infections with histoplasmosis contracted in laboratories indicate that infection with Histoplasma, whether of clinical significance or not, provides resistance to reinfection. The findings in 12 of the 13 epidemics are consistent with this view.

Emergency Infracostal Approach in Cardiac Arrest.—The high mortality in cases of cardiac arrest is due to delay on the part of the anesthetist in making the diagnosis and on the part of the surgeon in acting after the condition has been called to his attention. Minutes or even seconds may mean the difference between life and death. When cardiac arrest occurs during the course of an open chest operation, massage of the heart presents no great problem. It is in surgery elsewhere in the body that the problem of the quickest and most adequate emergency approach to the heart arises. Apart from the thoracic approach, the best known methods involve opening the peritoneum through a median epigastric incision and massaging the heart through the intact diaphragm, and when necessary, opening the diaphragm for more adequate exposure. The authors describe and illustrate with diagrams the infracostal approach for manual massage of the heart in cardiac arrest, and discuss the adjuvant measures useful in cardiac resuscitation. This emergency may arise in any surgical intervention. The infracostal approach, once learned, can be used with little hesitation by those unaccustomed to working in the thoracic or abdominal cavities. The method involves entering the chest through a left subcostal incision which allows access to the heart through a natural plane of cleavage lying posterior to the posterior rectus sheath and transversus abdominis muscle, and anterior to the peritoneum adjacent to the xiphisternal junction. Brief reports of the nine cases of cardiac arrest which occurred at the Southside Hospital, New York, in the past four years are presented, together with the plan of action which has been developed.

Regional Enteritis: Surgical Treatment.—The disease process of regional enteritis, which has been described also under such terms as regional ileitis, terminal ileitis, chronic cicatrizing enteritis, segmental enteritis, nonspecific granuloma of the intestine, chronic ulcerative ileitis, Crohn's disease, chronic enteritis, ileocolitis and pseudocancer, is nonspecific and the etiology is still obscure. It may involve any segment of the small bowel and/or the right half of the colon. The disease progresses through several stages. In the advanced stages a one-stage resection of the portions of bowel involved and an ileotransverse colostomy appears to be the treatment of choice. In poor risk patients and/or in those cases in which the disease process cannot be resected with safety, a short-circuiting operation consisting of complete ileal exclusion with an ileotransverse colostomy is the procedure of choice. It is suggested that this condition, as well as ulcerative colitis, nonspecific granuloma of the colon and peptic ulcer, may be initiated by an imbalance of portions of the autonomic nervous system. Upon this basis the favorable effects of vagotomy as reported by several clinicians may be explained. The authors are of the opinion that a right vagus resection inferior to the origin of the gastric branches, a bilateral splanchnicectomy, a lower dorsal and upper lumbar sympathectomy, and an excision of the left presacral parasympathetics would be a more logical procedure. Sixteen cases of regional ileitis are presented. In the early stages of the disease an appendectomy was performed in four patients during the acute episode. In the advanced group an ileal exclusion with an ileotransverse colostomy was performed in half of the patients, and in the others a one-stage resection of the diseased small bowel and right colon with an end-to-end ileotransverse colostomy was accomplished. There were no deaths and no recurrences.

Fibrosis of Sphincter of Oddi.—Cattell and Colcock of the Lahey Clinic point out that fibrosis of the sphincter of Oddi may be responsible for some of the symptoms in patients with cholelithiasis. It can best be demonstrated during exploration of the common duct. It may be overlooked unless exploration of the common bile duct is employed frequently during operations for cholelithiasis. At the Lahey Clinic exploration of the common bile duct is done in slightly less than half of all patients operated on for cholelithiasis, and approximately 20% of patients are found to have stones in the common bile duct. This high rate of exploration of the common duct has led to the discovery of an appreciable number of obstructions at the ampulla of Vater. The following methods are available as aids to the discovery of obstruction to the lower end of the common duct: (1) manometric pressure studies, (2) cholangiography, (3) operative exploration of the common bile duct, and (4) transduodenal exploration. Unrecognized fibrosis of the sphincter or stricture of the papilla may be responsible for recurrence or persistence of symptoms following cholecystectomy and may necessitate a secondary operation. The authors analyze observations on 49 patients with fibrosis of the sphincter or stricture of the papilla. These patients were selected after a careful study of the histories of a much larger group in whom the possibility of fibrosis was considered. Those cases in which the diagnosis was not substantiated, was indefinite or was questioned by the operating surgeon were excluded. The symptoms encountered in this selected group included all of those commonly associated with calculi in the biliary tract. The most conspicuous clinical feature was the occurrence of intermittent attacks of severe, right upper quadrant or upper abdominal pain, with the typical radiation to the back and to the shoulder. These attacks were frequently associated with anorexia, nausea, and vomiting. Forty-two of the 49 patients complained of these attacks. Twenty-seven patients gave a history of intermittent or persisting jaundice following the attacks of abdominal pain. Seven patients gave a history of chills and fever. With the demonstration of fibrosis of the sphincter, the operative procedures carried out in these 49 cases were as follows: forcible dilatation of the sphincter was performed in 35 patients, and in these a long T tube was inserted. Transduodenal sphincterotomy was performed in 10, and in each of these the long T tube was utilized. Dilatation of the sphincter with implantation of a short T tube was carried out in three patients. In one patient, choledochoduodenostomy was performed since a previous subtotal gastrectomy had been carried out. There was no operative mortality. Only two subsequent deaths have occurred, one a year later from chronic relapsing pancreatitis and pancreatolithiasis, and the second from carcinoma of the common duct. Complete relief of symptoms was obtained in 90% of the cases.

Survival Following Mastectomy.—Statistical studies were made on women on whom a radical mastectomy was performed at the Mayo Clinic for carcinoma of the breast from 1910 through 1934, with compiling of 15 to 40 year survival rates. Harrington was interested in determining certain factors that influence the prognosis as shown by the survival rates following operation. The prognosis of carcinoma of the breast following radical mastectomy appears related to many different factors, some of the more important of which are (1) the extent of the malignant involvement at the time of operation, (2) the degree of malignancy as shown by microscopic examination of the primary lesion, (3) the presence of other associated conditions such as pregnancy and lactation, (4) the general constitutional diseases such as diabetes, and (5) the age of the patient. The author knows of no method of determining what the prognosis will be in any individual case. Many patients have obtained the opinion that they are "cured" of malignant disease if, on examination five years after operation, no evidence of the malignant disease is found. A study of long term survival rates shows that local recurrence or metastatic lesions may occur 15 or more years after the operation. The cases available for the first tabulation numbered 4,637 patients with unilateral carcinoma of the breast on whom radical mastectomy was performed in 1934 or earlier; of these 4,563 (98.4%) were traced. Of patients traced for the respective number of years, 1,144 (25.1%) survived 15 or more years, 624 (17.6%) survived 20 or more years, 301 (12.6%) survived 25 or more years, 128 (9.3%) survived 30 or more years and 35 (6.9%) survived 35 to 40 qears. Of the 4,563 traced patients, 2,918 (63.9%) were found to have axillary nodal metastasis at the time of operation and 1,645 (36.1%) did not reveal nodal metastasis. Of the 2,918 who had axillary nodal metastasis, 351 (12.0%) lived 15 or more years, and of the 1,645 without axillary nodal metastasis, 793 (48.2%) lived 15 or more years. The author concludes that studies on long term survival rates following radical mastectomy for carcinoma of the breast show that it is impossible to determine definitely the prognosis in an individual case either before or at the time of the operation, and that patients with unilateral high grade malignant growths with metastasis as well as patients who develop a malignant growth in the remaining breast with metastasis subsequently may survive many years following operation.

*Temperatures Produced in Bone by Various Methods Used in Ultrasonic Therapy: An Experimental Study. L. F. Bender, J. F. Herrick and F. H. Krusen.—p. 424.

Temperatures Produced in Bone by Ultrasonic Therapy.—The femurs of anesthetized adult dogs were exposed to ultrasonic energy by various techniques of application. In one technique, the source of ultrasound was held stationary and the energy was either continuous or pulsed; in another technique, the source of ultrasound was moved back and forth over the desired area using only continuous energy. The temperatures of the cortex and marrow of the femur were measured by means of thermocouples. Extremely high temperatures were produced when the sound head was stationary and the energy was continuous. Pulsed energy provided a means of controlling the rise in temperature rather well. Stroking application of the continuously emitted ultrasonic energy provided the best control of the heating effect with the widest margin of safety. Ultrasound is used extensively in some European clinics, but since early investigations at the Mayo Clinic showed that dangerously high temperatures may be produced in the bones of experimental animals during short exposures to ultrasonic therapy, it was imperative to learn how to control these high temperatures before the therapeutic use of ultrasound could be considered.

Hemophilia-like Disease Following Pregnancy.—In a woman, aged 24, who had been in good health until August, 1949, a large hematoma developed over the right elbow after a minor trauma. One week later a painful hematoma appeared over the dorsum of her left foot. This was evacuated by her physician. The incision did not heal promptly because of continuous bloody oozing for three weeks. Several superficial and deep hemorrhages occurred in all extremities. The patient had given birth to a normal male infant three months before the onset of the present illness. There was no unusual immediate postpartum hemorrhage, but she had some vaginal blood loss for about one month. About three months after the onset of the disease, the patient had a partial clinical remission up to the time of her second pregnancy, which seemed to take a normal course until two weeks before the expected term, when gross hematuria developed, as well as extensive subcutaneous hemorrhages. A male infant, weighing 4,100 gm., was delivered on Nov. 6, 1950. From the second day after the delivery the patient bled for 41 days more or less profusely from vagina, necessitating transfusion of 89 units of blood (500 cc. each) in addition to 15 units of fresh serum. Administration of corticotropin and of stilbestrol had no effect on the hemorrhagic tendency. The patient underwent x-ray sterilization one week after cessation of the protracted hemorrhage. The failure of the fresh blood to influence the patient's coagulation mechanism led to the suspicion of a circulating anticoagulant, which was demonstrated by the direct method of Conley. This anticoagulant probably inhibited the antihemophilic globulin. The anticoagulant was demonstrated in the patient's second child during the first two and one-half months of life. The transplacental transfer of the anticoagulant and the similarity of this condition to hemophilia (resistant to therapy) following iso-immunization against antihemophilic globulin strongly suggest that an immunologic mechanism accounts for this abnormality. The patient recovered 18 months after her second delivery and 16 months after x-ray sterilization. The possible relation of the recovery to the sterilization remains unknown.

Comparison of Effects of Cortisone Administered Intraperitoneally and Subcutaneously.—Greenspan and associates administered cortisone acetate intraperitoneally and subcutaneously to adult male and female rats in doses of 1.25 to 3.75 mg. daily for periods of 40 to 48 days. Subcutaneously administered cortisone acetate produced the expected loss in body weight, and atrophy of the thymus and adrenal cortex. The same dosage of cortisone acetate intraperitoneally did not cause weight loss and produced no atrophy of the adrenals or of the thymus. The duration of the effect of a single dose of cortisone was then studied by following the urine output of rats which had been subjected to adrenalectomy and a daily water load. It was found that the intraperitoneal administration of cortisone acetate had an immediate and rapid effect on the restoration of water diuresis in these rats, whereas the subcutaneous administration of cortisone acetate had a slower and more prolonged effect. The data suggest that certain effects of cortisone acetate, such as weight loss and atrophy of thymus and adrenal cortex, may require a sustained corticoid level, as may be produced by subcutaneous administration of the drug. Other metabolic effects, such as the restoration of water diuresis in rats deprived of their adrenals and subjected to water tolerance tests, occur rapidly following intraperitoneal administration of cortisone acetate, but, perhaps because of the shorter duration of the effective corticoid level, there is no inhibition of growth or production of adrenal atrophy.

Sarcoidosis of Myocardium.—Sales reports a case of Boeck's sarcoid involving the myocardium, which brings to 18 the number of cases reported in the literature. The important data on the 18 cases are presented. The author's patient, a man, aged 20, was hospitalized on Aug. 9, 1948, complaining of abdominal distention, cough, productive of minimal amounts of white, frothy sputum, episodes of nocturnal dyspnea or orthopnea, and weakness of 1½ months' duration. Intermittent pedal edema was first noticed about two weeks prior to admission. Thereafter, the patient had mild anorexia and some febrile episodes. There was a 10 lb. (4.5 kg.) weight loss in one month. The patient gave a history of acute iritis in 1947 while in service in Korea, at which time a lymph node biopsy revealed Boeck's sarcoid. He denied venereal disease. He had episodes when his joints became hot, swollen and tender, the knee and ankle joints being those mostly involved. There was sinus tachycardia, and roentgenography of the chest revealed that the cardiac silhouette was enlarged in the transverse diameter, showing accentuation of the left auricular curve and increased rounding of the apex. A moderate degree of hypervascularity was present in the hilar region and at both bases. Both hands presented areas of osteolysis in several fingers. An electrocardiogram showed myocardial damage. The patient was kept semiambulant, and the temperature was normal. On the morning of the ninth day after admission, he complained of dyspnea and was advised to stay at bed rest. Shortly before noon, he had a sudden episode of severe dyspnea with coughing, productive of a cupful of blood. The dyspnea continued to increase, and he was placed in an oxygen tent at absolute rest. Rapid digitalization was carried out. About 2 p. m. complete vascular collapse occurred, from which the patient did not recover despite supportive measures. He died on the morning of the following day. A postmortem examination revealed chronic myocarditis (infiltration by sarcoidosis of Boeck), Boeck's sarcoidosis of tracheobronchial lymph nodes, passive congestion of lungs, and focal necrosis of liver. The consensus among authors, who have investigated this subject, is that death in cardiac involvement by sarcoidosis is usually due to extensive infiltration of the myocardium, with resultant fibrosis and cardiac failure.

Prevention of Rheumatic Fever: Immune Response in Streptococcic Infections.—Penicillin treatment of acute streptococcic pharyngitis results in a marked suppression of antibody formation. Studies were made on patients fulfilling the following criteria: the presence of exudative pharyngitis, history of onset of symptoms less than 31 hours before admission, and subsequent isolation of group A streptococci from the initial throat culture. Patients with a past history of rheumatic fever or chorea were excluded. A throat culture and a serum specimen were obtained from each patient at the time of admission and on the 14th, 21st, and 28th days from the onset of symptoms. Bacteriological and serological studies were performed. Antistreptolysis "O" titers were determined on all serums from each patient, and all tests were performed with the same lot of streptolysin and read by the same observer. Each of the 349 patients studied was assigned to one of four treatment groups according to a random sequence previously determined by a shuffled deck of cards. It was found that there is a correlation between the time of institution of penicillin therapy and the degree of suppression of antistreptolysin formation: the earlier the treatment the greater the suppression. Therapy, begun not later than 31 hours after the onset of symptoms of streptococcic pharyngitis, reduces the subsequent antistreptolysin response at 21 days by approximately 60%, while therapy begun five days after the onset of symptoms results in a 40% suppression. These observations support the hypothesis that the antigenic challenge during acute streptococcic pharyngitis occurs gradually, over a period of several days, and that an appreciable percentage of the total immune response develops as a result of antigen formed after the fifth day of disease. It is difficult to relate these data to the over-all problem of the prevention of rheumatic fever, since the present study was too limited to yield any direct evidence as to the effectiveness of delayed penicillin therapy in reducing the attack rate for this complication. It has been shown that there is a correlation between high convalescent antibody titers following streptococcal infections and the development of rheumatic fever. It would thus seem that early therapy of streptococcic infections would be advisable; delayed therapy, however, might exert some effect on the incidence of rheumatic fever.

Gastrointestinal Hemorrhage in Patients with Esophageal Varices.—Studies were made on 150 patients; cirrhosis had been proved in 146 by needle biopsy, in 1 by peritoneoscopic biopsy, and in 3 by necropsy. There were 134 cases of portal cirrhosis, 12 of postnecrotic cirrhosis, and 4 of cirrhosis due to infection with Schistosoma mansoni. Esophagoscopy revealed esophageal varices in 95. There was a history of serious hemorrhage from the upper gastrointestinal tract in 59 patients, 47 of whom were found to have esophageal varices. Among 91 patients without a history of hemorrhage, there were 48 cases of esophageal varices. Thirty-nine per cent of the patients with a history of hemorrhage had one or more lesions of the upper gastrointestinal tract in addition to varices that could have been responsible for the hemorrhage; 20% had other potential bleeding sites. Other lesions were associated in 22% of the 95 patients with varices. Duodenal ulcer was the commonest disease accompanying varices, having been found in 10% of all patients. Gastric ulcer, hiatus hernia, and esophagitis were each demonstrated in 7 cases. Twenty-one patients died during investigation, and all were studied at autopsy. Hemorrhage was the cause of death in 11 of the 21 fatalities, and in 7 of the 11 cases the hemorrhage originated in the esophageal varices. Two patients died of hemorrhage from acute erosive gastritis, one of hemorrhage from duodenal ulcer and one of hemorrhage from leukemic infiltration of the stomach. These observations imply that when a cirrhotic patient presents himself with a massive hemorrhage, esophageal varices are not necessarily the cause. Endoscopic and radiological studies of the upper gastrointestinal tract should be carried out in each cirrhotic patient.

Malignant Thymoma in Myasthenia Gravis.—The case presented is that of a man, aged 43, in whom a diagnosis of myasthenia gravis had been made in 1949. Roentgenograms of the chest revealed a tumor mass, which on needle biopsy proved to be a metastatic transitional cell carcinoma of the pleura. The patient received 2,400 r to the upper chest, and after this improved and was well regulated with 4 neostigmine (prostigmin) tablets (15 mg.) daily. In September, 1950, the symptoms returned, and he received an additional 6,000 r to the chest. He again improved, although he had to increase his neostigmine dosage to 7 tablets a day. In the spring of 1951 the patient suffered another relapse. Another physician confirmed the diagnosis of myasthenia gravis and increased the neostigmine dose to 20 tablets daily. Thymectomy was considered, but since roentgenograms of the chest indicated a widespread malignant neoplasm, plans for thymectomy were abandoned and the patient was given a third course of x-ray therapy. In December, the patient was readmitted to the hospital in acute respiratory distress, for which he was placed in a respirator. On a regime of frequent oral and subcutaneous administration of neostigmine, he steadily improved, and at discharge two months later was able to get along without a respirator. In July he was readmitted to the hospital because of sudden inability to swallow and breathe. He became progressively weaker despite massive doses of neostigmine and octamethylpyrophosphoramid. On Sept. 17, he became increasingly cyanotic and died. Autopsy revealed a malignant thymoma, with involvement of the mediastinum, right pleura, parietal pericardium, chest wall, diaphragm and peritoneum, and radiation fibrosis of the pleura and pericardium. Much confusion was caused in this case, because biopsy of an axillary lymph node had revealed neoplastic tissue. For a time the possibility that the mediastinal mass seen by x-ray represented an independent bronchiogenic carcinoma was considered, since malignant thymomas have never been known to undergo lymphatic metastasis. The autopsy demonstrated that the "metastasis" in the axilla actually was due to erosion of the chest wall by direct extension. The involvement of the peritoneum by extension through the diaphragm is unusual. Thymus glands are found normal in about 85% of cases of myasthenia. The exact mechanism by which this disease is produced remains unclear, but there is evidence that a humoral factor interferes with transmission of the nerve impulse across the neuromuscular junction. The possible relation of this to intracellular electrolyte abnormalities and to the therapeutic use of corticotropin is discussed.

Funnel Chest: Indications and Time for Operation.—The authors sent a questionnaire as to the fate of adult patients with untreated funnel chest to a group of physicians and surgeons with wide experience in diseases of the chest. The questionnaire asked what proportion of patients with severe degree of funnel chest develop cardiac, pulmonary, or psychological disability, whether the life span of such patients is shortened, and whether operative repair in childhood should be advised. Twenty-five questionnaires were answered completely enough to be useful. The majority felt that among adult patients with severe funnel chest there are some who suffer from cardiac or respiratory disability. There was a feeling that many of these patients undergo psychological trauma. Twenty-three of the 25 physicians feel that operative correction of a severe degree of funnel chest should be undertaken in childhood. Observations on eight patients operated upon by the author are reviewed. Most operations recommended in the past are modifications of the procedures described by Brown. The first, which he calls "simple" and recommends for infants, is that of freeing the inner surface of the lower portion of the sternum from its posterior attachments. The second procedure, which had been described by Garnier, consists of the removal of the backward-projecting segments of the lower costal cartilages together with the performance of a wedge osteotomy across the upper sternum to permit the sternum to come forward. Varying modifications of this latter operation include resuturing the rib ends to the sternum, with use of a transplanted-bone strut to hold the sternum forward and various methods of traction. In two infants, 6 and 10 months of age, respectively, the author used the "simple" technique of Brown and little improvement resulted. In six other patients the more radical technique was used and the results were satisfactory in the five who were between 2 and 6 years old, whereas in a boy of 15, the correction of the deformity was incomplete. The author recommends in severe cases of funnel chest radical surgical treatment when the child is between 2 and 6 years old.

Herpes Simplex Infections.—Primary herpetic gingivostomatitis has come to be recognized as one of the common infectious diseases of childhood. The virus of herpes simplex was first implicated as the etiological agent in 1938 by Dodd, Johnston and Buddingh. Buddingh and associates review studies pursued during the course of several years in the pediatric clinics and wards of Vanderbilt University Hospital. The virus of herpes simplex was isolated and identified and the specific serologic response to primary infection was demonstrated in 52 children ranging from 1 to 3 years of age. These cases provided the material required for the development of techniques and methods. In a detailed study of 12 patients the virus was recovered from the mouth and stools during the acute stage, convalescence, and for varying periods thereafter. The average time during which virus could be recovered from these sources was 23 days after the onset of the disease. Virus could not be recovered from the blood or spinal fluid, but patients were not available for study before the third day of the disease. Neutralizing antibodies to herpes simplex were first demonstrated in the serum from the fourth to seventh day of the disease. The antibodies attained a maximum level during the second or third week. The maximum antibody concentration was not maintained and dropped to relatively low levels over varying periods. Herpes simplex virus was recovered from the mouths of persons presenting no clinical evidence of herpetic infection; it was recovered from 7% of 571 normal individuals of various ages; from one infant out of 97 under 6 months of age, from 20% of 72 children of 7 months to 2 years, from 9% of 199 children 3 to 14 years of age, and from 2.5% of 185 adults. Neutralizing antibodies were demonstrated in the serum of 43% of white and 71.4% of Negro children in the 7 month to 2 year age group. In adults 90% of white and 96% of Negro individuals had antibodies to herpes in the serum. Natural active immunity appears to be established at an earlier age in the segments of the population in which the highest carrier rate was demonstrated. Neutralizing antibodies were demonstrated in the serum of 76% of white infants and in 90% of Negro infants 6 months of age and under. The placental transmission of neutralizing antibodies was demonstrated. Approximately the same level of antibody was found in the maternal and placental serums.

Blood Alcohol Concentrations in Relation to Time of Wine Drinking.—Experiments were conducted on medical students in good health and ranging in age between 23 and 26 years. The wine had an ethyl alcohol content of 11% by volume. The amount given in each experiment corresponded to 0.5 cc. of ethyl alcohol per kilogram of body weight. The meal given provided 1,898 calories. When wine was given with or after meals, lower blood alcohol concentrations were observed than when it was given on an empty stomach. The effect of a meal on blood alcohol concentrations lasted about four hours. When wine was taken on an empty stomach in three or in six doses, the peak of the blood alcohol curve appeared later than when it was given in a single dose. When wine was given in three or in six doses during a meal, the resulting blood alcohol curves were definitely lower than those that follow similar ingestion of wine on an empty stomach. The peak of the curve following the drinking of wine on a full stomach appeared earlier than when taken on an empty stomach. This earlier appearance of the maximum blood alcohol concentration seems to indicate that retarded absorption cannot explain the lowering of the blood alcohol curve induced by a meal ingested before the administration of the alcoholic beverage. These observations uphold the view that alcoholic beverages should be ingested with or soon after meals if it is desired to utilize their qualities and minimize the risks of possible untoward effects.

Adenolipomatosis of Thyroid: New Type of Goiter.—The patient, a 15-year-old youth, had had a lump in the neck since birth. The lump increased gradually. At the age of 9, the boy was given tablets for a goiter. He has three sisters and five brothers; one of the brothers had a fatty tumor removed from the side of his neck while in military service. Physical examination of the boy revealed normal conditions, except for the large tumor, which gave the impression of a cystic adenoma. On operation the neck tumor was found to be yellow in color and much softer than thyroid tissue. A rather large portion of thyroid was left on the right side to prevent myxedema. Microscopic examination of the surgical specimen, which weighed 253 gm., revealed that the tissue of the right lobe was not arranged in lobules; follicles of various sizes were separated by dense fibrous stroma. Large islands of mature fat tissue alternated with thyroid tissue. Amyloid could not be demonstrated by special stains. The histological diagnosis was congenital lipoadenomatosis of the thyroid. The glandular and adipose tissue were intermingled at a ratio of one to four. There was evidence of chronic thyroiditis. It is believed that the goiter was caused by admixture of fat tissue in thyroid tissue during the first months of embryonal life. The authors call attention to a report by Simard, which appeared in a French Canadian publication in 1945. It described a new type of goiter, which he called sclerolympholipomatosis of the thyroid. The authors feel that the clinical and structural aspects of their case greatly resemble those of Simard's case. The admixture of fat was not associated with amyloid of the thyroid as in the cases of Oberlin and Fuller.

Papilloma of the Gallbladder with In Situ Carcinoma.—True papilloma of the gallbladder is rare. Tabah and McNeer estimate its incidence at about 1 in 100 cholecystectomies. It is sometimes confused with cholesterol polyps or with the epithelial proliferations seen in chronic cholecystitis. The diagnosis of true papilloma of the gallbladder requires cholecystography. The authors describe observations on four patients with papilloma of the gallbladder, who were recently observed at the Memorial Cancer Center in New York City. These cases are especially noteworthy, because noninfiltrating carcinoma in situ originated in the papilloma in three of the patients. In the opinion of most writers there is no known relationship between the two lesions. The authors feel that cholecystectomy is the only effective treatment of papilloma of the gallbladder, because this condition is capable of giving rise to symptoms, because it is frequently associated with cholelithiasis and cholecystitis, and most important, because it is a precancerous lesion, in which malignant degeneration is quite likely.

Blood Volume Studies in Normal Humans.—The study was divided into three parts. In part 1 it was demonstrated by using iodinated human serum albumin that the three-sample withdrawal method gives the more consistent results. Making use of the disappearance curve accounts for the loss of the material from the blood stream, the loss due to diffusion of the material into the lymph, and the variations in the initial mixing rate. In part 2 the values for the plasma volume obtained by utilizing Evans' blue or iodinated human serum albumin show a good degree of reproducibility in the same patient in spite of a number of technical difficulties. In part 3 the plasma and total blood volumes obtained by using radioactive phosphorus tagged red blood cells, iodinated human serum albumin, and Evans' blue were compared simultaneously in the same patient. The first test gives the lowest values, the second the middle values, and the third the highest. By using the above data it was demonstrated that the total body hematocrit is lower than the peripheral vessel hematocrit. On the basis of theoretical considerations the authors believe it is better to determine the total blood volume by adding the red cell mass determined by radiophosphorus tagged red blood cells and the plasma volume obtained with iodinated human serum albumin. Both are direct measurements and do not introduce the error of the peripheral vessel hematocrit.

Polyvinylpyrrolidone in Burn Shock.—The hydrophilic character and osmotic activity of polyvinylpyrrolidone are factors that increase and maintain circulating blood volume. The ability of the polyvinylpyrrolidone molecule to bind or adsorb toxins and the fact that it is inexpensive, completely sterilizable, producible in unlimited quantities, nonantigenic, and well tolerated assure polyvinylpyrrolidone an important role in burn therapy. Cordice and associates review their experience with polyvinylpyrrolidone in Ringer's solution in the treatment of eight severely burned patients. The areas involved by the burns varied from 20 to 75% of the body surface. From 1,000 to 3,000 cc. of polyvinylpyrrolidone in Ringer's solution was infused in from one to eight and one-half hours. All patients treated with the polyvinylpyrrolidone solution on admission showed recovery from shock, decrease in hematocrit, improvement of toxicity, and increases in urinary output. In three cases the hemoglobinuria cleared in periods of 12, 15, and 48 hours respectively, but the improvement and the fall in hematocrit were not maintained as well as in hemorrhagic and traumatic shock. This may be explained by the continued fluid and protein loss from the burned areas. Early improvement with fall in hematocrit was always observed, and in none of the four patients who died was death caused by shock or hemoconcentration. Three of the fatal cases showed laboratory evidence of impairment of liver function. There was no evidence of toxic action of polyvinylpyrrolidone; a reaction following infusion of the drug in one patient seemed more likely to be due to the increase in blood volume with toxins from burned areas being drawn into the blood stream. A sharp decrease in plasma protein occurred in two patients; this should be guarded against with adequate diet, intravenous plasma, albumin, and blood transfusions with early skin grafting. The results substantiate previously published experiences and indicate that polyvinylpyrrolidone is a valuable adjunct in the early treatment of burns.

Coin Lesions of Lung.—Storey and associates list the following as the characteristics of coin lesions of the lung: 1 to 5 cm. in size, round or oval in shape with sharply circumscribed borders, surrounded on all sides by normal appearing lung, producing no symptoms, homogeneous in density or containing calcium, and solitary. They present observations on 40 patients with this lesion. The nodule in each case was discovered upon routine x-ray examination of the chest. In all except two of the cases surgical excision was resorted to. Tuberculoma was the usual preoperative diagnosis. A malignant tumor was encountered in seven instances. There was no surgical mortality, and the postoperative morbidity was minimal. A spread did not occur in any of the patients whose lesion proved to be of tuberculous origin. Five cases are presented to illustrate the hazards of the watchful waiting program sometimes advocated in cases of this type. Spontaneous resolution of these nodules cannot be anticipated. If of tuberculous origin, as they often are, they will not respond to medical treatment. These lesions are not influenced by streptomycin, because the drug does not penetrate the fibrous wall of tuberculomas. Although it cannot be stated with statistical accuracy just how frequently these lesions cavitate and spread, it is well known that such a disaster occurs occasionally. Of much greater importance is the fact that until histological study of the excised mass has been carried out, the diagnosis can only be presumptive. Experience has shown that it is unsafe to manage these patients on the assumption that a coin lesion is probably benign. In a collected series of 362 patients with histologically verified coin lesions, including those reported in this paper, neoplastic disease was found in 108 cases. The authors feel that a cancer rate of nearly 30% makes it difficult to defend any therapeutic regimen that does not provide for their prompt removal.

Intrauterine Anoxia as Cause of Fetal Death During Labor.—Although toxemia, prolonged labor, traumatic delivery, maternal anemia, excessive analgesia and anesthesia, and placental accidents have long been recognized as causes of intrauterine anoxia and fetal death, relatively little attention has been directed toward labor itself. Taylor believes the production of anoxia by over-forceful labor may well account for some of the so-called "unexplained fetal deaths in utero." He cites the obstetrical histories of three women, which suggest that when there are exceedingly strong, hard, and frequent labor contractions, intrauterine anoxia may occur, leading to "unexplained deaths." Precipitate, or strong and forceful, rapid, driving labor added to the known deficiencies inherent in placental physiology can bring about fetal death in utero. This may happen repeatedly in the same patient. All three women had a forceful type of driving labor typified by strong pains lasting at least a minute and recurring at about two-minute intervals. One of the women was conscious of strong Braxton Hicks contractions, which may have been of significance. In all three instances the appearance of meconium-stained amniotic fluid served as an indication of intrauterine fetal anoxia. Unfortunately, once fetal distress has been noted, the damage may already have occurred, although subsequent treatment may enhance the possibility of recovery. Elective cesarean section seems to be the method of choice in preventing a second fetal death.

Segmental Cystectomy in Vesical Carcinoma.—The authors report on 16 patients on whom segmental cystectomy was practiced for vesical carcinoma in a Copenhagen hospital between the years 1944 and 1951. The total number of patients with cancer of the bladder admitted in this period was 46, of whom 16 were inoperable and 14 were treated with cystotomy plus electrocoagulation or with total cystectomy. Three women and 13 men are reported on here. More than half of them were over 60 years. In nine cases the resection necessitated transplantation of one ureter to some other part of the bladder. There was no postoperative death, and complications were limited to one case of protracted suprapubic fistula with pubic osteitis. In four cases the tumor was localized to the apex, in eight to the right side of the bladder, and in four to the left. In 10 of the cases the tumor was macroscopically papillomatous, and in 6 it was nodular and ulcerative. In 50% of the cases the duration of illness was from six months to two years; two patients had previously (six months and two years before) been treated for benign papilloma. On reexamination, from six months to eight years after the operation, eight patients were free from recurrence, six had a relapse, and in two this aspect was uncertain. The observation period for three of those who did not relapse was 6 to 12 months, and for four it was over 3 years. The papillomatous tumors of relatively low malignancy and slight penetration into the bladder wall are nonrelapsing. Also the localization of the lesion plays a role, as all the cases in which the tumor was localized to the apex of the bladder have been free from relapse regardless of the degree of malignancy and depth of penetration. Segmental cystectomy, which is merely a local radical treatment, has advantages over total cystectomy. The efficacy of segmental cystectomy can be increased by earlier diagnosis and surgical treatment.

Valvulotomy for Mitral Stenosis.—Sixty patients were operated on for mitral stenosis in a Copenhagen hospital between January, 1950, and July, 1952. Their ages ranged from 14 to 54 years. Nine patients died, but of 45 patients less than 40 years of age only 2 died. Of the 14 patients who had symptoms of cardiac incompetence at rest at the time of operation, 4 died. Owing to the questionable reliability of the diagnostic criteria, the authors also operated on patients who were supposed to have some mitral incompetence. It proved possible to diagnose the majority of the cases of mitral insufficiency by stethoscopic examination. The accuracy of the diagnosis is improved by examination of the pulmonary capillary pressure curves. As a rule, the valvulotomy has been performed with the finger alone, an instrument having been used in only four cases, but in the future an instrument will be used in all cases in which the valve is found to be leathery and elastic. The authors preferred to use the finger unprotected by a glove, because one gets a better impression of the anatomical details and of the amount of regurgitation. Thirty-six patients were reexamined 4 to 22 months after the operation. Of these, 24 were improved to an extent that they could be placed into a "better" group, according to the classification of the American Heart Association. Those who did not improve were mainly those with severe mitral insufficiency and with leathery, elastic valves. Repeated attacks of pulmonary edema and hemoptysis are indications for the operation. A history of peripheral emboli, and combined stenosis and regurgitation and rightsided heart failure are only relative contraindications in patients below 40 years of age; in patients above 40 years the indications must be stricter. Contraindications are: active rheumatic infection, complicating aortic failure and pronounced incompetence indicated by stethoscopic observations and by the pulmonary capillary pressure curves.

Incidence and Treatment of Myeloid Leukemia.—The occurrence of chronic myeloid leukemia is reported in 24 male and 32 female patients who were admitted to the Royal Cancer Hospital in London between 1936 and 1951. The average age of onset of the disease for the 56 patients was just over 44 years. Comparison with groups of cases of chronic myeloid leukemia reported by other workers suggested a shift towards a higher age of onset of the disease and a change in the ratio of men to women towards a higher proportion of females than males. Statistical figures showed a consistent rise in the incidence of myeloid leukemia, probably not entirely due to improvements in diagnosis and recording. The duration of the disease, whatever treatment was employed, has remained remarkably constant over the last 30 years and is between 3 and 4 years. X-ray irradiation alone or in combination with chemotherapy has been used in most of the cases. The irradiation technique usually adopted consisted of irradiation of the spleen only; the average dose given was between 50 and 150 r twice a week, up to an average total of between 500 and 1,500 r in four to eight weeks, though in some patients a good remission was obtained with a smaller dose. Comparison of the methods of treatment used showed that better results have been obtained with external roentgen irradiation than with other methods so far employed. Radioactive phosphorus has been used in too few cases for any conclusions to be drawn. Of the various chemotherapeutic agents all except 1,4-dimethanesulphonyloxybutane (Myleran) have been discarded by the author on account of the relatively poor remissions achieved and the high incidence of toxic effects. The preliminary trials of Myleran in doses of 4 mg. daily by mouth have been encouraging. It remains to be seen whether the bone marrow will show repeated favorable responses to this agent. There is no evidence as yet that any of the methods of treatment can be regarded as a cure, but it is probable that some prolongation of life is obtained in a few patients and certain that in many more treatment can so alter the quality of life as to turn it from one of invalidism into one enjoyable and worth while.

BOOK REVIEWS

The Founders of Neurology: One Hundred and Thirty-Three Biographical Sketches Prepared for the Fourth International Neurological Congress in Paris. By eighty-four authors. Edited by Webb Haymaker, M.D., Chief, Neuropathology Section, Armed Forces Institute of Pathology, Washington, D. C. With bibliographical and editorial assistance of Karl A. Baer, bibliographer, Army Medical Library, Washington, D. C. Cloth. $10.50. Pp. 479, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

This book is a compilation of biographies of the important figures in neurology of the past 100 years, excluding those who are still living. The biographies were written by various neurologists, most of whom have had some personal contact with the person they describe. The book does not attempt to give a connected history of the development of neurology but is restricted to short biographies of 133 physicians, mainly German, French, English, and American, with a photograph of each. These biographies are divided into groups according to the special field of interest as follows: neuroanatomists, neurophysiologists, neuropathologists, clinical neurologists, and neurosurgeons. The sketches are too brief to give anything but a glimpse of the life and personality of the subject, but on the whole they are well written; and the photographs are clearly reproduced.

Forewords were written by Dr. Henry A. Riley, vice-president of the Fourth International Neurological Congress, Col. J. H. McNinch, director, Army Medical Library, and Brig. Gen. Raymond O. Dart, director, Armed Forces Institute of Pathology. A short chapter that defines the academic terms used in the biographies gives the reader insight into the academic hierarchy of France, Germany, and England. There is a brief list of references at the end of each biography that gives a few of the more important publications of the persons and, in some cases, sources for a more complete biography. There is a full and adequate index, and the book should be of value to all physicians interested in the nervous system.

Thoracic Surgical Management. By J. R. Belcher, M.S., F.R.C.S., Consultant Surgeon at London Chest Hospital, London, and I. W. B. Grant, M.B., M.R.C.P., Assistant Physician, Edinburgh Northern Hospitals, Edinburgh. Foreword by Sir Clement Price Thomas, K.C.V.O., F.R.C.S., Surgeon to Westminster and Brompton Hospitals, London. Cloth. $3.50. Pp. 196, with 65 illustrations. [Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2]; Baillière, Tindall & Cox, 7-8 Henrietta St., Covent Garden, London, W.C.2, 1953.

This small book is full of useful information clearly and concisely expressed. It is intended principally for senior residents in thoracic surgery or those in general surgery who come in contact with thoracic problems only occasionally. The book is well printed, well illustrated by clear line drawings, and is thoroughly recommended, not only to the comparatively junior resident in surgery but to all who are interested in surgery of the chest. Throughout the advice proffered is sound, sane, and common sen ould be in the libraries of all hospi done.

vitamins are interesting and commend themselves to the clinician. The review of dietary neuropathies, including beriberi, alcoholic peripheral neuritis, polyneuritis gravidarum, acrodynia, and Wernicke's encephalopathy, develops the point that the earliest signs of thiamine deficiency in some patients may be peripheral nerve damage, in others, disturbances of the cardiovascular system predominate, and, in a small minority, Wernicke's encephalopathy is the initial abnormality. Pediatricians will find the discussion of the problem of absorption and transportation of fat-soluble vitamins particularly interesting because of the low store of these vitamins in the newborn. In the sections on the hormones, experimental aspects of study predominate. Of particular importance are the sections dealing with the effects of steroid hormones on the enzymes involved in tissue oxidation and carbohydrate metabolism.

Manual of Comparative Anatomy. By Osmond P. Breland, Ph.D., Professor of Zoology, University of Texas, Austin. Second edition. Cloth. $4.50. Pp. 256. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farrington St., London, E.C. 4, 1953.

The first edition of this manual was published 10 years ago. As the title indicates, the book is to be used by students of comparative anatomy. This edition has been carefully revised and rewritten to conform with modern ideas. In addition to the classic animals, dogfish, necterus, and cat, it includes sections on the lamprey, perch, turtle, and pigeon. The book is well written and free from inaccuracies. Boldface type for the names of structures is used extensively. The author should be complimented on his fine descriptive style. The instructions for dissection are clear and definite. Indeed, the only drawback of this book is the absence of illustrations. Perhaps there is some merit in this, but, in laboratories where facilities do not exist for the study of all the representative species, it is advisable for the student to have illustrations of the important aspects of the species not subjected to dissection. This book should be most helpful to students of comparative anatomy and will also serve as a reference for research workers.

On Burns. Compiled and edited by Nathan A. Womack, M.D. Participants: Dr. William Altemeier, et al. Publication number 165, American Lecture Series, monograph in Bannerstone division of American Lectures in Surgery. Edited by Michael E. De Bakey, M.D., Professor of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Plastic Surgery Division. Editor: James Barrett Brown, M.D., Professor of Clinical Surgery, School of Medicine, Washington University, St. Louis. Cloth. $5.50. Pp. 178, with 7 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book represents a virtually verbatim transcript of the symposium on burns held at Iowa City in May, 1951. This symposium, which was held in conjunction with a National Civil Defense effort, might be thought of as laying the backround in medicine and surgery that should underlie any ve or logistical steps taken in civil defense. The fibrous dysplasia existed in the femur and in the adjoining soft parts a myxofibroma. The author cites two other cases from the literature, in which osteitis fibrosa was probably brought on by fibrous dysplasia, and in these cases likewise myxofibromas were found in the surrounding musculature. Myxofibromas are found also in von Recklinghausen's neurofibromatosis, which seems to be related to fibrous dysplasia. Nevi of a "coffee with milk" color as well as incretory disorders such as pubertas praecox have frequently been found in association with fibrous dysplasia, and since such lesions are found also in neurofibromatosis, it is assumed that these entities are related.

Prevention of Peritoneal Adhesions by Cortisone.—Lyall investigated the preventive effect of cortisone on the formation of peritoneal adhesions in guinea pigs. Various substances were investigated for their effect in producing strong peritoneal adhesions in experimental animals, and it was found that a 50% suspension of talc in isotonic sodium chloride solution with the addition of mandarin black produced firm adhesions. Daily intramuscular injections of cortisone acetate for 7 days before and for 16 days after the injection of the talc suspension prevented or greatly restricted the formation of peritoneal adhesions, whereas the control animals, which received the talc suspension but no cortisone, all developed peritoneal adhesions. These experiments confirm in guinea pigs what was described in rats by others, namely, that adhesion formation can be prevented by the parenteral use of cortisone. It is not certain whether this can profitably be applied to the human subject, because of the possibly harmful effect of the cortisone on the healing of the abdominal wound. There is still some doubt about the exact method by which cortisone prevents adhesion formation. The obvious explanation would be its power of retarding fibroplasia. But there is evidence of other possible factors. The amount of clear peritoneal exudate is increased and that may contain some "spreading factor." Increased intestinal motility might also play a part.

Cortisone in Treatment of Carditis. J. Mowbray.—p. 178.
Rheumatic Carditis—Its Diagnosis and Prevention. R. Mulcahy.—p. 185.

Hypertrophic Pyloric Stenosis in Children.—McNicholl reports on 143 infants with a pyloric tumor palpated by an experienced pediatrician on more than one occasion. There were 117 males and 26 females, corresponding to the usual sex incidence of 4 or 5 to 1. Medical treatment was attempted in 88, and was successful in 57. Surgical treatment was used alone in 55 cases, and in 31 others it followed varying periods of medical treatment. Selection of one type or other of treatment was made according to various pediatricians' personal views, and not according to the criteria advised by the author. Surgical treatment is indicated in infants in whom vomiting commences during the second week or earlier, the weight is below that at birth, severe obstruction appears suddenly and there is severe dehydration. Suitable correction of the dehydration must, of course, precede the operation. Severe infection or generalized disease and slight obstruction or late onset are contraindications to surgical treatment. Indications for medical treatment are vomiting that commences in the fourth week or later, and which has persisted for three weeks or more when the child is first seen and the weight loss is nevertheless small; also moderate or severe alkalosis (after suitable correction). Contraindications to medical treatment are severe obstruction and dehydration, and perhaps hematemesis. The feeding procedure during medical treatment is outlined. Treatment with atropine methyl nitrate (Eumydrin) is described. Surgical treatment is discussed only from the pediatrician's point of view, with emphasis on the preoperative and postoperative management. Three infants died, two from complicating infections some weeks after successful surgical treatment. The author feels that approximately half of all infants with pyloric stenosis can be satisfactorily treated by medical means, with special emphasis on atropine methyl nitrate.

Radiation Nephritis.—Nephritis may result when all the renal tissue is included within the therapeutic field of deep x-rays. Twenty-seven patients with radiation nephritis were studied clinically. The syndromes observed were acute and chronic radiation nephritis, benign hypertension, and late malignant hypertension. Thirteen cases of acute radiation nephritis were studied in detail. From the start of radiotherapy there was an asymptomatic latent period of 6 to 12 months (usually eight months). The main clinical features were edema, urinary changes, hypertension, anemia, cardiac enlargement, headache, retinitis, dyspnea, nausea and vomiting, lassitude, nocturia, and drenching sweats. Edema was found in the majority of patients. Generalized edema, shown by a rapid increase in weight, was an early symptom in some. Pleural effusions and ascites occurred in the fatal cases only. The urinary changes included persistent albuminuria, low specific gravity of urine, and the presence of urinary casts or a few erythrocytes. Hypertension usually developed early, but fell to normal if the patient survived for six months. Severe and refractory anemia was an early and constant feature. It was normochromic and normocytic, and not due to marrow aplasia or hemolysis, but rather to renal failure. Cardiac enlargement occurred at an early stage in all cases. Renal function improved gradually in the patients who survived. There was a relationship between the level of the blood urea and the progress of the anemia; as renal function improved the need for blood transfusion became less. A bad prognosis was indicated by severe edema, or by a blood urea level over 100 ml. Death was due to left ventricular failure, congestive heart failure, hypertensive encephalopathy, and uremia. All patients who survived had residual chronic nephritis, with the features of chronic glomerulonephritis. A condition resembling benign essential hypertension occurred in four cases. Malignant hypertension developed long after radiotherapy, in two cases 18 and 24 months after radiotherapy; both patients died within seven weeks of the onset of symptoms. Autopsy in four of the seven fatal cases showed a layer of fibrous tissue between the peritoneum and kidneys. The kidneys were usually of normal size, but the capsules were thickened. There was widespread fibrosis between atrophic tubules, damage to almost all the glomeruli, and fibrin necrotic lesions of arterioles.

Parenteral Administration of Hexamethonium in Hypertension.—Hexamethonium, pentamethonium, or a homologue of hexamethonium have now been in use for over three years in the treatment of hypertension. Most investigators have used the oral route, and there is much difference of opinion concerning the benefit obtained. Morrison reports observations on 39 hypertensive patients who were treated with hexamethonium bromide by subcutaneous injection. The patients were drawn from the complicated-essential, malignant, or renal groups of hypertension; uncomplicated cases were not included. Five patients died during the treatment and it was discontinued for various reasons in 6 others, but 28 patients received regular therapy for periods varying between 3 and 15 months and were seen at least once a month. After the development of a variable amount of tolerance to the drug during the first four to eight weeks, all patients could be stabilized on a dose which gave an average blood pressure level much below that found in the control period. Reduction in the mean systolic pressure ranged from 20 to 90 mm. Hg and in the mean diastolic pressure from 8 to 40 mm. Hg. Hypertensive headaches were relieved in 15 out of 19 cases, and lessened in frequency and severity in the other four. Giddiness disappeared and encephalopathic attacks did not recur, except in one instance. Shortness of breath from cardiac causes was generally improved and in several cases there was relief from acute cardiac dyspnea. Diminution in cardiac volume was demonstrated in five of seven cases, and in seven out of 16 cases electrocardiographic signs of left ventricular hypertrophy were altered towards the normal. Retinopathy was strikingly improved in all severe cases, papilledema subsiding, and extensive exudates and hemorrhages becoming reabsorbed, with restoration of normal vision after about six months' treatment. One instance of coronary thrombosis and two major and two minor cerebral vascular accidents occurred during treatment, but in two of the latter the blood pressure was high at the time. No evidence of increased damage was found among patients with impaired renal function. Three patients, after successful treatment of from seven to 15 months, were found to have dyspnea and symmetrical opacities in the lung fields. The pathogenesis of these pulmonary changes is still obscure. Although these three patients required large doses of the drug, others who required as much or more have remained well. The author feels that the risk of these complications should not be regarded as a contraindication to the use of hexamethonium in severely ill hypertensive patients.

Farmer's Lung.—The condition designated as "farmer's lung" appears to be commonest in regions with high rainfall in the hay-gathering season and primitive methods of harvesting and storage in closed barns. Much information was obtained from several practitioners of the area where farmer's lung is observed. The cases reviewed consist of six confirmed radiologically, and six probable cases that were radiologically inconclusive. The clinical picture is characterized by a nonspecific lung irritation which may follow exposure to mouldy vegetable dusts of any type, but mainly contact with poor quality hay. Although before the severe reaction there may be minor bronchitic episodes following short contact, a distinction must be drawn between true farmer's lung and an asthmatic attack following exposure to mouldy dust. The main feature of the disease is breathlessness and cyanosis which develop within 12 hours of exposure. The onset is sudden, and may be associated with a rigor, vomiting, a dry cough, and a feeling of suffocation. The picture resembles that of acute edema of the lungs, but there is no cardiac embarrassment. Widespread fine crepitations are heard, but no localized areas of consolidation are detected. Clearing of radiological and physical signs usually requires six to eight weeks. After the first two or three weeks the breathlessness becomes less distressing, but then loss of weight and night sweats occur. After three months the patient appears to be well, but there is a tendency for the condition to recur on re-exposure. Treatment has little effect and spontaneous clearing is observed in untreated cases. Farmer's lung is similar to coniosporiosis, byssinosis, and diffuse granulomatous pneumonitis. The author is of the opinion that the condition is a nonspecific interstitial lung reaction to some material in the fungus-laden dust, rather than a true fungous infection.

Toxic Effects of Phenylbutazone.—The drug can be given by mouth or by intramuscular injection, but as the majority of patients treated by the authors were outpatients, the former route was usually employed. Patients were warned of possible side-effects and were asked to restrict their salt intake; those who gave a history of peptic ulcer or cardiovascular or renal disease were excluded. Three patients were suffering from diabetes, which was not affected by phenylbutazone. The series consisted of 109 patients (79 women and 30 men), their ages ranging from 12 to 73 years. Of these, 86 had rheumatoid arthritis, 19 osteoarthritis, and 3 gout. One patient had a ligamentous strain of the knee. The drug was given to 102 patients by mouth in tablets containing 0.2 gm. in daily doses ranging from 0.2 to 1.2 gm. (average dose 0.6 gm.). Seven received intramuscular injections of 1 gm. on four alternate days, followed by weekly injections. All patients were seen first at weekly, then fortnightly, and, later, monthly intervals. A check was kept on the white blood cell count and the sedimentation rate. Symptomatically 59 patients were greatly improved by phenylbutazone, but in none was there a fall in the sedimentation rate. In 15 improvement was only slight, in 25 the drug had no beneficial effect, and in 10 toxic reactions occurred before any therapeutic effect could be noted. Forty-six patients had toxic reactions. These occurred in nearly half of those deriving great benefit. The authors feel that although toxic reactions severe enough to make further therapy dangerous were observed in nearly half the patients, its trial in chronic disabling conditions seems justifiable, since there are a large number of patients who derive benefit from it without toxic manifestations.

Simultaneous Occurrence of Fibrous Dysplasia (Jaffé-Lichtenstein) and Extraosseous Fibromyxoma.—Braunwarth points out that in 1938 Jaffé and Lichtenstein described fibrous dysplasia as a separate entity, rejecting a relationship to osteitis fibrosa generalisata, despite the fact that the histological aspects of both diseases are similar. The concept of Jaffé and Lichtenstein has been widely accepted, but Albright and collaborators observed cases in which in addition to bone changes cutaneous lesions existed, and in some cases incretory disturbances in the form of pubertas praecox were observed. Uehlinger in 1940 described necropsy studies on a patient with polyostotic fibrous dysplasia. This patient also had fibromyxomas in the thigh and leg. The case presented in this paper concerned a woman, aged 56, who asked medical advice about a swelling on the left thigh that had developed in the course of the last year. This case resembles the one described by Uehlinger in that fibrous dysplasia existed in the femur and in the adjoining soft parts a myxofibroma. The author cites two other cases from the literature, in which osteitis fibrosa was probably brought on by fibrous dysplasia, and in these cases likewise myxofibromas were found in the surrounding musculature. Myxofibromas are found also in von Recklinghausen's neurofibromatosis, which seems to be related to fibrous dysplasia. Nevi of a "coffee with milk" color as well as incretory disorders such as pubertas praecox have frequently been found in association with fibrous dysplasia, and since such lesions are found also in neurofibromatosis, it is assumed that these entities are related.

There was widespread fibrosis between atrophic tubules, damage to almost all the glomeruli, and fibrinoid necrotic lesions of arterioles.

BOOK REVIEWS

The Founders of Neurology: One Hundred and Thirty-Three Biographical Sketches Prepared for the Fourth International Neurological Congress in Paris. By eighty-four authors. Edited by Webb Haymaker, M.D., Chief, Neuropathology Section, Armed Forces Institute of Pathology, Washington, D. C. With bibliographical and editorial assistance of Karl A. Baer, bibliographer, Army Medical Library, Washington, D. C. Cloth. $10.50. Pp. 479, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

This book is a compilation of biographies of the important figures in neurology of the past 100 years, excluding those who are still living. The biographies were written by various neurologists, most of whom have had some personal contact with the person they describe. The book does not attempt to give a connected history of the development of neurology but is restricted to short biographies of 133 physicians, mainly German, French, English, and American, with a photograph of each. These biographies are divided into groups according to the special field of interest as follows: neuroanatomists, neurophysiologists, neuropathologists, clinical neurologists, and neurosurgeons. The sketches are too brief to give anything but a glimpse of the life and personality of the subject, but on the whole they are well written; and the photographs are clearly reproduced.

Forewords were written by Dr. Henry A. Riley, vice-president of the Fourth International Neurological Congress, Col. J. H. McNinch, director, Army Medical Library, and Brig. Gen. Raymond O. Dart, director, Armed Forces Institute of Pathology. A short chapter that defines the academic terms used in the biographies gives the reader insight into the academic hierarchy of France, Germany, and England. There is a brief list of references at the end of each biography that gives a few of the more important publications of the persons and, in some cases, sources for a more complete biography. There is a full and adequate index, and the book should be of value to all physicians interested in the nervous system.

Thoracic Surgical Management. By J. R. Belcher, M.S., F.R.C.S., Consultant Surgeon at London Chest Hospital, London, and I. W. B. Grant, M.B., M.R.C.P., Assistant Physician, Edinburgh Northern Hospitals, Edinburgh. Foreword by Sir Clement Price Thomas, K.C.V.O., F.R.C.S., Surgeon to Westminster and Brompton Hospitals, London. Cloth. $3.50. Pp. 196, with 65 illustrations. [Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2]; Baillière, Tindall & Cox, 7-8 Henrietta St., Covent Garden, London, W.C.2, 1953.

This small book is full of useful information clearly and concisely expressed. It is intended principally for senior residents in thoracic surgery or those in general surgery who come in contact with thoracic problems only occasionally. The book is well printed, well illustrated by clear line drawings, and is thoroughly recommended, not only to the comparatively junior resident in surgery but to all who are interested in surgery of the chest. Throughout, the advice proffered is sound, sane, and common sense. It is a book that should be in the libraries of all hospitals in which thoracic surgery is done.

Vitamins and Hormones: Advances in Research and Applications. Volume X. Edited by Robert S. Harris, Professor of Biochemistry of Nutrition, Massachusetts Institute of Technology, Cambridge, G. F. Marrian, Professor of Medical Chemistry, University of Edinburgh, Edinburgh, and Kenneth V. Thimann, Professor of Plant Physiology, Harvard University, Cambridge. Cloth. $8. Pp. 421, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1952.

The contents of this volume of a valuable series suggest a reversal of the title to more properly represent the 80% of the textual material devoted to the endocrine system. The editors remark: "This is a reflection of the greater amount of research being conducted at present in the hormone than in the vitamin field." Nevertheless, the sections devoted to vitamins are interesting and commend themselves to the clinician. The review of dietary neuropathies, including beriberi, alcoholic peripheral neuritis, polyneuritis gravidarum, acrodynia, and Wernicke's encephalopathy, develops the point that the earliest signs of thiamine deficiency in some patients may be peripheral nerve damage, in others, disturbances of the cardiovascular system predominate, and, in a small minority, Wernicke's encephalopathy is the initial abnormality. Pediatricians will find the discussion of the problem of absorption and transportation of fat-soluble vitamins particularly interesting because of the low store of these vitamins in the newborn. In the sections on the hormones, experimental aspects of study predominate. Of particular importance are the sections dealing with the effects of steroid hormones on the enzymes involved in tissue oxidation and carbohydrate metabolism.

Manual of Comparative Anatomy. By Osmond P. Breland, Ph.D., Professor of Zoology, University of Texas, Austin. Second edition. Cloth. $4.50. Pp. 256. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farrington St., London, E.C. 4, 1953.

The first edition of this manual was published 10 years ago. As the title indicates, the book is to be used by students of comparative anatomy. This edition has been carefully revised and rewritten to conform with modern ideas. In addition to the classic animals, dogfish, necterus, and cat, it includes sections on the lamprey, perch, turtle, and pigeon. The book is well written and free from inaccuracies. Boldface type for the names of structures is used extensively. The author should be complimented on his fine descriptive style. The instructions for dissection are clear and definite. Indeed, the only drawback of this book is the absence of illustrations. Perhaps there is some merit in this, but, in laboratories where facilities do not exist for the study of all the representative species, it is advisable for the student to have illustrations of the important aspects of the species not subjected to dissection. This book should be most helpful to students of comparative anatomy and will also serve as a reference for research workers.

On Burns. Compiled and edited by Nathan A. Womack, M.D. Participants: Dr. William Altemeier, et al. Publication number 165, American Lecture Series, monograph in Bannerstone division of American Lectures in Surgery. Edited by Michael E. De Bakey, M.D., Professor of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Plastic Surgery Division. Editor: James Barrett Brown, M.D., Professor of Clinical Surgery, School of Medicine, Washington University, St. Louis. Cloth. $5.50. Pp. 178, with 7 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book represents a virtually verbatim transcript of the symposium on burns held at Iowa City in May, 1951. This symposium, which was held in conjunction with a National Civil Defense effort, might be thought of as laying the background in medicine and surgery that should underlie any administrative or logistical steps taken in civil defense. The participants, in addition to the editor, Dr. Womack, are experts in their field of burn study and treatment. Their remarks and informal comments are of great interest, even though nothing particularly outstanding or new is disclosed in the discussions. The sections are planned as an over-all review or status report on the problem of burns. The presentation is quite effective. The reader of this book should be the civil defense worker who wants to know something about burns. The book is too advanced for the medical student, and it is too elementary for the postgraduate student of surgery who, as an assistant resident or a resident, examines and treats burns. It is unfortunate that the discussions were prepared and transcribed without any bibliography, because the inexperienced reader will now have to trace through other channels the writings that are so extensively referred to in the text.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

QUERIES AND MINOR NOTES

TRANSFUSIONS IN INFANTS

To the Editor:—*A point has arisen in the question of typing infants and newborn infants for transfusions (routine transfusions as well as replacement transfusions [Rh]). Is it necessary to type, cross match, and determine the Rh factor of the blood given a newborn infant, or is it proper and safe to give Rh-negative, type O blood routinely and repeatedly without typing and cross matching? Why?*

William L. Rumsey, M.D., Elizabeth, N. J.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Although it is correct that in the normal newborn infant the development of isoimmune bodies is usually not very pronounced, normal babies do not receive blood transfusions. When one is dealing with infants with disease processes it seems advisable to follow the same routine procedures for blood transfusions as are established for adults. Typing and cross matching of recipient and donor, regardless of the age, is recommended.

Answer.—It is not good practice to give group O, Rh-negative blood routinely to all newborn infants for transfusion purposes without typing and cross matching tests, even though this is a relatively safe procedure. The question of selecting donors for newborn babies is fully discussed in a book by A. S. Wiener (Blood Groups and Transfusion, ed. 3, Springfield, Charles C Thomas, Publisher, 1943, pp. 69-71). In emergencies, the washed red blood cells of the mother may always be used for newborn babies since the baby's blood never contains antibodies capable of reacting with the mother's red blood cells. There is even slight objection to this if the mother is Rh positive and the baby Rh negative, although newborn babies are relatively incapable of forming antibodies and being sensitized. The recommended procedure is to group newborn babies, test for the Rh factor, and see that the infant receives compatible blood. In cases of erythroblastosis, of course, Rh-negative blood is used even though the baby is Rh positive. In cases of erythroblastosis caused by A-B sensitization, group O blood is used even though the baby belongs to group A or group B. In the unusual cases caused by Hr, Hr-negative blood should be used even though the baby is Hr positive. There is no simple answer to the question, since every case must be individualized.

POLIOMYELITIS

To the Editor:—*Six weeks ago we had three cases of acute anterior poliomyelitis in two weeks at Bryan Air Force Base, Texas. During this period and for a month following we discontinued the use of spinal anesthesia, especially since one patient was a young woman who had been delivered with spinal saddle block anesthesia two weeks prior to the onset of her disease. We have had no cases at this base in the past month, but more cases are being reported in surrounding counties throughout Texas. We would like to know whether it is safe to resume use of spinal anesthesia or whether it should be discontinued altogether.*

William W. Wiltberger, M.D., Bryan, Texas

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—On present evidence no one could say with assurance whether the use of spinal anesthesia in the case described had any connection with the subsequent development of poliomyelitis. No similar case has been found in the literature, and it seems likely that the sequence of events was due to chance rather than cause and effect. Occasionally poliomyelitis has occurred shortly after parenteral injection of various agents. The only data available that are statistically significant relate to injections of agents commonly given to children. With some of these, at least, there is a demonstrated tendency for paralysis to occur selectively in the limb that was the site of the injection. It is not yet clear how this effect is influenced by such variables as the nature and volume of the inoculum, or the site and depth of needle puncture. Nor is it clear, from data on man, that injection of any of the agents studied increases the risk of poliomyelitis (Greenberg, Abramson: *New York State J. Med.* **52:**2624-2629 [Nov. 1] 1952). Some recent animal experiments of Bodian (*Fed. Proc.* **12:**437 [March] 1953) show that intramuscular injections of cortisone or of gelatin, if given during a state of viremia, increase the incidence of paralytic poliomyelitis, with selective paralysis of the injected limb. Bodian suggests that injured nerve fibers at the site of injection may provide an entry for circulating virus into nerve tissues and a route for invasion of the central nervous system. To what extent these findings would apply to a spinal puncture in man can only be conjectured at present. In human patients the probability of a viremia existing at the time of puncture would in any circumstances be small. It would presumably be less for adults than for children (because of acquired immunity) and would depend on the local prevalence of poliomyelitis infection at the time. H. K. Faber, at the meeting of the American Pediatric Society in Atlantic City, May 8, 1953, presented a theory that postinoculation paralysis results from introduction of virus from contaminated skin surfaces or needles at the site of puncture and that introduction of virus by this means can be avoided by prior sterilization of the skin with a 2% tincture of iodine solution.

Answer.—Almost certainly there is no connection between the spinal saddle block anesthesia given two weeks before the onset of acute anterior poliomyelitis and the disease. There have been instances where spinal anesthesia was given to patients with unrecognized prodromal symptoms of poliomyelitis in whom paralysis developed from one to five days later, but this was probably coincidental. Of course, one should avoid the use of spinal anesthesia when there are suspicious prodromal symptoms of poliomyelitis. Spinal anesthesia is contraindicated in a patient who has or has had poliomyelitis with residual paralysis, just as this form of anesthesia should be avoided in anyone who has a history of central nervous system disease. There is no reason why spinal anesthesia should not be used in the area in spite of the occurrence of acute poliomyelitis.

ASCORBIC ACID

To the Editor:—*I read an article in the April, 1952,* Archives of Pediatrics *by Dr. W. J. McCormick of Toronto, Canada, on the chemotherapeutic value of large doses of vitamin C. It was stated that the smoking of one cigarette neutralizes 25 mg. of ascorbic acid in the body, the amount contained in an average-sized orange. If this statement is correct, it would appear that many persons who smoke heavily may have vitamin C deficiency. Can ascorbic acid be bought without a prescription in drug stores in tablets containing up to 250 mg.? Dr. McCormick says the drug is harmless, even in doses as high as 1,000 mg. given intravenously. Is there any evidence that there are less upper respiratory tract infections in areas, such as Florida, in which more citrus fruits are eaten and hence the vitamin C intake is higher?*

M.D., Philadelphia.

Answer.—That the smoking of one cigarette neutralizes 25 mg. of ascorbic acid in the body is not generally accepted as a fact. Adequate data concerning the effect of smoking on the metabolism of vitamin C have not been published. Ascorbic

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

acid tablets can be bought in drug stores without prescription. Several grams of ascorbic acid can be given orally or parenterally daily without producing evidence of toxicity. Ascorbic acid is promptly absorbed from the gastrointestinal tract, and any amount in excess of bodily need is rapidly excreted in the urine. If there is a lower incidence of respiratory tract infections in such areas as Florida, it is unlikely that this is attributable to the availability of citrus fruits in these areas. Although severe ascorbic acid deficiency (scurvy) in animals or man leads to heightened susceptibility to infections and, conversely, the presence of infection may increase the requirement for ascorbic acid, there is no conclusive evidence that the administration of excessive quantities of ascorbic acid enhances resistance to infectious agents.

GILLES DE LA TOURETTE'S DISEASE

To the Editor:—*The reply to the question under the above heading in* The Journal (**151:***962 [March 14] 1953) repeats the myth that Tourette's disease is identical with or similar to latah, "Jumping," and miryachit. There can be no doubt that Tourette's disease is, in itself, a neurological entity, but latah, "Jumping," and miryachit are local variations of a fundamental psychiatric anomaly that are best, in view of existing confusion, called simply the latah reaction. In a paper in the* Journal of Mental Science (**98:***515 [Oct.] 1952) entitled "The Latah Reaction: Its Pathodynamics and Nosological Position," I gave reasons for the above view and also pointed out that the latah reaction is essentially a fright neurosis, with minimal hysterical features, found in persons whose power of adaptation and mastery are limited by a low standard of civilization.*

CARE OF INFANT OF A DIABETIC MOTHER

To the Editor:—*In Queries and Minor Notes, May 2, 1953, is a question on care of the infant of a diabetic mother. The answer advocates oral administration to the infant of 10 cc. of 5% dextrose in water immediately after birth and then every one or two hours during the first few days, in addition to the regular feedings. It is suggested further that 5% dextrose in sodium chloride solution be injected in each buttock if the dextrose is not taken by mouth.*

This answer stems from the period prior to recognition of the fact that neonatal hypoglycemia is physiological during the first few days of life in infants of both diabetic and nondiabetic mothers. Despite the low blood sugar levels, newborn infants do not have symptoms of hypoglycemia, such as occur in older children and adults. Causes other than hypoglycemia, such as atelectasis and cerebral hemorrhage, have been discovered as responsible for the attacks of cyanosis that often occur in newborn infants of diabetic mothers. Cyanosis in these infants responds more readily to the use of suction and administration of oxygen and carbon dioxide than to administration of glucose, even intravenously. It has been found that routine administration of glucose by mouth does not affect the infant's blood sugar level appreciably. Regardless of weight and size, the infant of a diabetic mother behaves like a premature baby. It is usually edematous. It should not receive regular feedings, as mentioned in the answer; these should be withheld until the edema and respiratory difficulty, if present, are abated, which may take as long as six days. Some physicians advocate very small intramuscular doses of mercurial diuretics (0.1 cc.) to hasten the correction of the edema.

Leon M. Levitt, M.D.
14 E. 16th St., Brooklyn 26.

To the Editor:—*In* The Journal, *May 2, 1953, page 105, is a question about the care of a newborn infant of a severely diabetic mother. The answer given needs amplification. The question indicated an interest in the use of intravenously administered glucose solutions. Actually, this is seldom needed, because few, if any, of these infants have hypoglycemia that requires correction in the neonatal hours. The primary cause of death is pulmonary atelectasis secondary to hyaline membrane formation. Other causes are congenital heart defects and perhaps chemical and hormonal factors that are not well understood.*

Treatment of the infant involves first the use of gentle aspiration of the mouth, nose, and pharynx and perhaps the passing of a catheter into and aspiration of the stomach shortly after delivery, especially if the baby has been born by cesarean section. My routine procedure, following aspiration in the delivery room, consists of placing the infant, regardless of weight or maturity, in a humidified, oxygenated incubator, where it is left undisturbed, except for further aspiration, if needed. Nurses are asked to observe the color and respiration carefully and to watch for convulsive movements during the first 24 hours of life. Blood glucose determinations are not made routinely, for the normal newborn infant of a nondiabetic mother may have a blood glucose level of 50 mg. per 100 cc. or less. Furthermore, there is presumably in the newborn infant the same endogenous release of glycogen for the regulation of blood glucose as exists in the older infant.

In only one of the last 30 infants of diabetic mothers observed by me or my associates did hypoglycemia cause difficulty, and in that infant there was an associated congenital cerebral defect. Loss of weight during the first few days is greater than in other newborn infants, but this is due to overhydration of the infant before birth and, usually, does not necessitate either oral or parenteral fluid replacement. Even with this weight loss, clinical evidence of hypoglycemia is rarely noted. Careful observation of the infant is needed, for signs of respiratory embarrassment may not commence for 6 to 24 hours after delivery. The use of penicillin and possibly streptomycin soon after birth merits consideration as a prophylactic measure against secondary pulmonary infections. Lastly, the mother's dose of insulin should be reduced during the 24 hours preceding delivery, and two or three small doses of regular (quick-acting) insulin should be given instead of the customary single dose of one of the slow-acting insulins. Administration of a glucose infusion to the mother during delivery is also advised in the case of a severely diabetic woman.

Alfred E. Fischer, M.D.
73 E. 90th St., New York.

RECURRENCES OF RHEUMATIC FEVER

To the Editor:—*The question in Queries and Minor Notes in* The Journal, *July 11, 1953, concerning the prevention of recurrences of rheumatic fever is answered in a manner that, we believe, has improper emphasis. The reply disregards, in essence, the statements of the American Heart Association Council on Rheumatic Fever and Congenital Heart Disease* (J. A. M. A. **151:***141 [Jan. 10] 1953). While the precise pathogenesis of acute rheumatic fever is still unknown, there is little question that most attacks follow pharyngeal infections with group A hemolytic streptococci. That recurrences can be prevented by the prevention of streptococcic infections has been shown in many studies. It has also been demonstrated that the proper treatment of streptococcic sore throats with penicillin results in a markedly decreased incidence of both recurrent and primary attacks of clinical rheumatic fever. Since about one-half of such streptococcic infections, for various reasons, do not receive the attention of a physician, it would appear necessary for chemoprophylaxis to be given continuously the year around if one were to succeed in preventing recurrences of rheumatic fever. In our present state of knowledge, there appears to be little question that such a program is proper if not mandatory. There may be some question about the ideal method for providing the penicillin, but the best of present information supports the doses recommended in the publication referred to above. Such factors as housing, crowding, altitude, weather, diet, etc., are probably of importance to the pathogenesis of rheumatic fever only as they are related to the epidemiology of streptococcic disease.*

Harry A. Feldman, M.D.
Harold B. Houser, M.D., Syracuse, N. Y.
